Whether you're an experienced packeteer or a newcomer wanting to explore packet for the first time, this is what you've been waiting for! Thanks to a breakthrough in digital signal processing, we have developed a tiny, full-featured, packet modem at an unprecedented low price. The BayPac Model BP-1 transforms your PC-compatible computer into a powerful Packet TNC, capable of supporting sophisticated features like digipeating, file transfers, and remote terminal access. **NOW** is the time for YOU to join the **PACKET REVOLUTION!**

Figure 1. Connecting the MBR1635 and the power FET.

marcial power supply instead of a PV array. Just connect the power supply to the PV terminal and set its voltage to 16 volts. The supply should have current limiting, as a low battery may

draw more current than the supply can produce.

I presented the controller as a project to get one's feet wet with power MOSFETs. I hope everyone has

picked up a few ideas along the way. The market is always changing, and the power MOSFET is certainly not being left out. Today, the buzzword is 3.3 volt systems. Everywhere you look, you'll see a new specialized chip to work on 3.3 volts. The power MOSFET of yesterday required +10 volts to fully turn on. Now on the market are the newer power MOSFETs that you can saturate with TTL logic (+5 volts). The aim is to have a fully saturated gate with as little as 3.3 volts. The "on" resistance of the power MOSFET continues to fall. It's now possible to get "P" channel power MOSFETs with an $R_{DS(ON)}$ of less than 0.05 ohm. They're expensive, about \$19 each, but the price will continue to fall as more and more are made.

Even though the devices are rather rugged when soldered in the PC board, I've found that those with the lower RDS(ON) seem to be more picky about static discharges than FETs with a higher RDS(ON). I can't prove this theory, but all of the FETs I've zapped have been ones with a very low RDS(ON). So, when you're working with these devices, take time to avoid static discharges. Wear a wrist ground strap and use a grounded soldering iron.

You may also have some trouble locating power MOSFETs. It seems they're in quite a demand as a major component in the anti-lock brake sys-

tems used in today's automobiles. A number of times I've ordered IRFZ42s only to be told they're out of stock and back-ordered.

If you can't find all the parts needed for this project, drop me a line. I have most of the hard-to-get components in stock here. This includes the terminal block and the trimmer, as well as the power MOSFETs.

Coming Up . . .

In the coming months, I hope to have a working version of an amplifier based on N5NNN's version. I don't want to re-invent the wheel, but there will be some added features to this rig. Stay tuned.

Also, if you have built the little Two-Fer from two months ago, I'll be showing you a small self-contained T/R controller using a power MOSFET instead of the QSK circuit on the Two-Fer board. It will work in just about any home-brew QRP rig. I'm sure you'll find it interesting.

Of course, let's not forget that this month it's Field Day. Keep an ear open for me on 40 meters running home-brew gear this year. Solar-powered, of course, with battery backup at night.

Next month we'll look at some repairs to the very popular Ten-Tec Argonaut 509. Although it's a rather old rig by today's standards, it's still a QRP workhorse.

QUALITY THAT'S AFFORDABLE

Tri-Ex is pleased to announce the reduction in price on the most popular models of quality Tri-Ex towers for the Amateur radio enthusiast. The overwhelming acceptance of the listed models has made it possible for Tri-Ex to pass on substantial savings to our valued customers.

LM-470 WAS **NOW!**

ANY RIG—ANY ANTENNA AUTOMATICALLY SMARTUNER™

Let's get frank about HF antennas. Most hams try to put resonant antennas up for every band. For those with the room, great! But for the rest of us, limited to perhaps a single long wire or some other compromise antenna, the SGC SMARTUNER is the ideal solution. Its onboard computer selects exactly the right inductance and capacitance from more than one half million possible combinations. Then it remembers the setting so your rig will return in a jiffy and leave you with the ball to exacting

Edge Of Space Sciences

One of the more prolific amateur radio balloon groups can be found in the Denver, Colorado, area. With over 100 members, the Edge Of Space Sciences (EOSS) group is a nonprofit corporation that promotes science and education via amateur radio and high altitude balloon experiments. They provide high school and university students with an opportunity to conduct scientific experiments at "near-space" altitudes in excess of 20 miles (100,000 feet). The EOSS group provides the transportation and balloon payload framework, and organizes the launch and recovery for these experiments. This is a great opportunity for all participants to learn how to design, launch and track what is for all practical purposes a small spacecraft (actually an "edge of space" craft).

Research and Education Possibilities

Students now have a chance to conduct a variety of experiments that were simply unavailable or unaffordable in the past, when they could fly their experiment either on the space shuttle or on a very large NASA research balloon. These options usually require a lot of lead time and the waiting list is long.

Through the efforts of the many members of EOSS, students now have a relatively easy and inexpensive way to study the atmosphere, environment and space.

EOSS has conducted over 11 balloon flights since its incorporation, all with extensive student involvement.

Gaining from their flight experience, they have developed a reliable system that relays telemetry (altitude, temperature, system voltage and experiment data) back to mission control through the use of an onboard flight computer that sends down the data via packet and CW. They usually fly an ATV system on 426.25 MHz, providing a live TV camera view of the earth, the balloon and the experiment. They can up-link commands to the payload to activate and control experiments, rotate the mirror in front of the TV camera, or release the payload from the balloon for recovery.

Their current system is called the EOSS "Shuttle" and is a reusable framework for downlinking ATV and telemetry (see Figure 1 for system details). EOSS has flown a number of flights using a standard weather balloon. Unfortunately, these balloons burst at peak altitude and the payload immediately parachutes back. Although very inexpensive, this type of flight usually lasts about two to three hours, and the time in near-space is limited to a short period.

To allow their package to float at altitude for extended periods of time, the EOSS group has been using a plastic "zero-pressure" style of balloon. Although more expensive than a rubber weather balloon (but not unaffordable), this balloon starts out at liftoff as a large bag of plastic with a small bubble of helium in the top (see Photo A). It is fully inflated at peak altitude and vents out excess helium until it reaches an equilibrium. It will stay at altitude until it loses excess solar lift. After sunset, it will start a slow return to earth unless ballast is dropped. One of EOSS's first flights using this type of balloon stayed up 18 hours and landed over 200 miles away, in Nebraska, around 5 a.m.! The dedicated (and

Photo A. The sixth EOSS flight used a large zero-pressure balloon to carry a student solar telescope aloft. It was dubbed the "Humble Telescope."

travel-weary) chase team had followed it through the night and quickly recovered it.

These long-duration flights have many possibilities. Imagine a VHF FM or an ATV repeater with a consistent 400-mile range! Some of the more advanced EOSS payloads have included a solar telescope, a Loran C position downlink and a gimballed mirror TV camera system to allow the ground crew to remotely control the view from the payload (downlinked via ATV on 426.25 MHz).

Their next mission will fly a student experiment which will test differential GPS (Global Positioning System).

National Balloon Symposium

In an effort to bring together members of the various balloon groups, educators, students and scientists to share information, EOSS is sponsoring the first ever National Balloon Symposium. It will be held at the Holiday Inn at the Denver International Airport (Denver, Colorado) from August 20-22.

Friday night will be a social event for viewing payloads and launch videos, and meeting the other attendees. On Saturday, papers will be presented by nationally prominent balloon experimenters, educators, scientists and authors. Topics will include such

Photo B. The payload for the first EOSS flight carried a TV camera and ATV transmitter aloft. The flag was used as a rudder. (packaging by Dave Cllngerman W6OAL).

Photo C. During the tenth flight, this payload carried an experiment designed by university students.

areas as the general history of ballooning, payload construction and testing, flight systems, regulations, tracking and recovery, high altitude physics and plenty of tales and yarns about various flight experiences. EOSS will sponsor a luncheon at the Saturday meeting. A balloon payload workshop will be offered on Sunday, as well as (if the weather permits) an opportunity to launch and track an actual balloon experiment.

For information about the symposium, contact Edge Of Space Sciences (EOSS) at 376 West Caley Circle, Littleton CO 80120; Tel: (303) 794-5624.

To submit a paper for inclusion in the proceedings and/or for presentation at the symposium, please contact Ann Trudeau, 15487 E. Bates Ave., Aurora CO 80013; Tel: (303) 690-1669. Any group that would like to launch their own payload on Sunday from the symposium, please coordinate with Marty Griffin, 1647 E. Geddes Circle N., Littleton CO 80122; Tel: (303) 794-3458.

If you are interested in starting up your own balloon group or have an interest in this kind of amateur radio activity, this should be a fascinating event. Thanks to EOSS president, Jack Crabtree AAØP, for the above information.

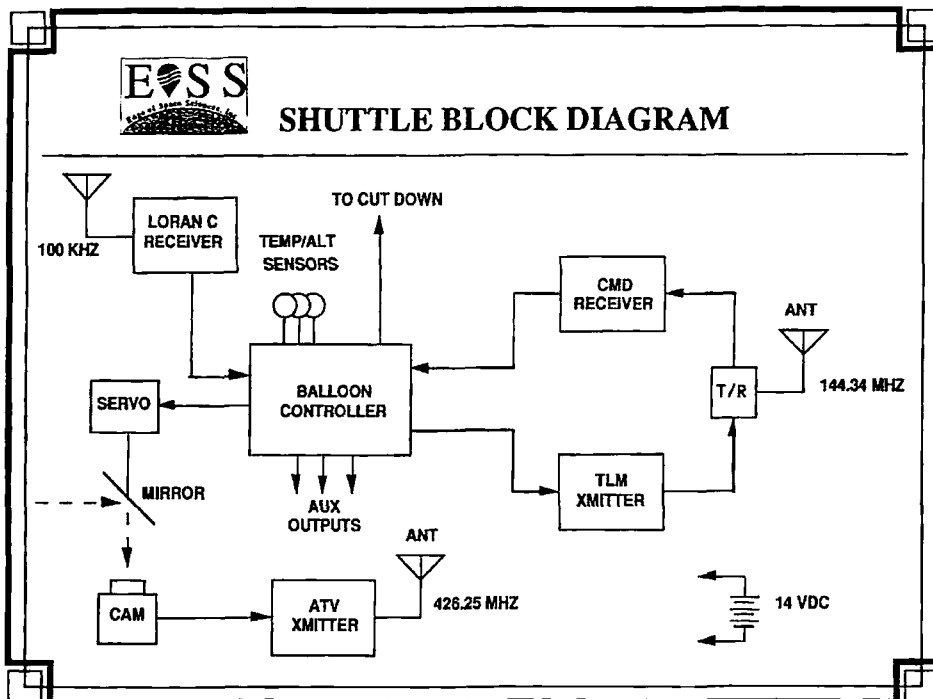

Figure 1. The EOSS "Shuttle" package consists of a reusable framework for downlinking video and telemetry from student experiments. Command capability is included via a VHF uplink.

Microwave Moonbounce

Microwave moonbounce might not be everyone's cup of tea, at least not those who think microwave communications is line-of-sight only (implying short distances only). Long-distance communications is quite possible on the microwave bands, and to prove it let's go to the extreme: moonbounce. This path covers communications of over a half-million-miles. Possible? Yes, indeed. As a matter of fact, communication was made between WA7CJO in Phoenix, Arizona, and G3WDG and G4KGC in England on 10 GHz moonbounce. What follows is the account from G3WDG covering this contact and some of the methods he used to make it.

"On January 31, 1993, at 2230, G3WDG and G4KGC made two EME QSOs on 10 GHz. This is believed to be the first made on this band from the UK. The initial QSO was with WA7CJO in Phoenix, Arizona, at 2230. This was the second attempt. The first test on Jan-

uary 30 was partially successful as WA7CJO was heard at good signal strength at G3WDG's location for a one-way contact.

"The antenna in use in the UK was a 10-foot solid dish (Andrew 11 GHz version) mounted on an E/Az mount originally intended for satellite TV use but modified for motor drive. The dish was scraped off from a local electronics company where G3WDG used to work. During Christmas 1992 the foundation was laid for the tower and a week before the first test the dish was put into its mount and the elevation azimuth drive motors were also installed.

"The rest of the equipment consisted of a Hughes 28 watt TWT amplifier. WA5VJB and KY7B helped in acquiring this tube and in refurbishing the power supply. The TWT was driven by a G4DDK-004 and a G3WDG-001-designed transmitting module for use in the 10 GHz system. An early design G3WDG-004 prototype HEMPT preamp was used to drive the receive converter, and a G3WDG-002 10 GHz converter was used in the 10 GHz converter. (Note: Designations such as G3WDG-xxx indicate different modules that are

Figure 1. Basic EME moonbounce operation. Transmit and receive dish antennas are shown with a 1 degree beam width. Note: Reflected signal is much wider on return to earth. A = the transmit dish's beamwidth; B = the receive dish's beamwidth; C = the return bounce to earth.

available for 10 GHz construction in the UK).

"The output from the 10 GHz converter was split into two channels. One was fed into G3WDH's shack, feeding the 144 MHz receive system. The other feed supplied a 2-MHz-wide 70 dB gain block connected to an indicating power meter. The function of the power meter feed was to give visual indication when the dish was correctly aimed at the moon.

"The power meter was then used to read 'moon noise,' the increase in noise when the dish antenna is accurately aimed at the moon. The reference noise is that which occurs when the dish is pointed on nothing specific (cold sky). An increase in the residual noise reading on the power meter (when aimed at the moon) is a usable indicator that your antenna is in proper position for moonbounce work.

"In actual operation the moon noise measured 1.7 dB above cold sky noise at G3WDG's location, with a 1.25 dB noise figure preamp being used. A more sensitive (lower noise figure) preamp (0.75 dB noise figure) was not used at the time because it might be destroyed by the transmitting equipment. It was held in reserve for later tests.

"The standards for indicating signal readability on moonbounce signals are the 'O' and 'M' reports. These are standard EME signal reports: 'O' signifying easy copy, and 'M' difficult copy. In RST terms, G3WDG copied WA7CJO at 539, and later copied SM4DHN at 529. SM4DHN would have been 3 dB stronger if all stations were using the same polarization for the dish feed systems. Note: Both G3WDG and WA7CJO were using linear feeds; SM4DHN was using circular polarization.

"Signal reporting is done with 'O' and

'M' reports in CW; these are the standard EME signal reports used. I presume they use them because they are quick and easy to identify what is going on in a very fast action. When 10 GHz signals bounce off the moon they have a rough note similar to rain scatter, but not as rough. This is a CW signal with all the dots and dashes there, but with a rough note.

"It's kind of hard to explain this rough note. It is not pure CW as you hear on low frequency bands but, as I refer to it, a sort of a 'CUSH' sound. If you slur the word 'CUSH' the resulting noise resembles the returned CW note, with a short 'CUSH' being a 'DOT' and a long 'CUSH' being a dash.

"Back to the power meter and the tracking part of the system. The moon noise tracking method was recommended by WA5VJB and KY7B and it worked extremely well. With this system in place it was very easy to keep the dish exactly on the proper heading, despite the very narrow antenna beamwidth (about 0.7 degree). A sighting telescope had also been fitted to the dish mount but, as always happens in the UK, it was 100% cloudy on the 30th and 31st. The dish positioning had to be updated by reading moon noise on the power meter at least every minute to keep the dish in proper orientation, pointing at the moon.

"An alternative to checking dish aiming and system receive operation is to check sun noise. You guessed it! Cold sky noise is when the dish is pointing at nothing in particular. Sun noise is of course much larger than moon noise and whichever you use, both work well. The reports from the UK indicate that with the sun at a very low sun position they were able to get 3 dB sun noise

with the sun shining through a hedge."

Concerning the use of smaller dishes, Charlie G3WDG states that both WA7CJO and SM4DHN should be receivable on dishes smaller than his 10-footer. His calculations show that readable signals should be obtained with dishes as small 1.2 meters (that's four feet in diameter), with a very good low-noise preamp, of course. Charlie states that both WA7CJO and SM4DHN have quite good equipment: WA7CJO has a 5 meter dish and 350 watt output, and SM4DHN uses a 6 meter dish and 70 watts of power on 10 GHz.

Another interesting feature with moonbounce is that you do not need another station to be there to determine if you can successfully bounce signals off the moon. This can be verified by your own station. You transmit towards the moon and a few seconds later you should be able to hear your "echo" reflected back at you. Due to Doppler shift, the return frequency is not the same as your transmitted frequency, but is shifted higher in frequency. In this test from G3WDG he received the echo 14 kHz shifted in frequency. The signal was weak yet had quite consistent echoes, loud enough to have worked if it had been another station.

This should get you spurred up into thinking about EME contacts on microwave. Contacts of this sort are not limited to 10 GHz, but rather any band between VHF and microwave are possible. The equipment required is kind of specialized, but with a little scrounging you can put it together, if you put your mind to it.

EME Moonbounce Program

Path loss considerations need to be taken into account. The formulas are a

little bit intimidating, but there are many different computer programs available that will do the calculations for you. All you have to do is answer the questions prompted by the program and it will give you the needed approximations. I have a simple program that is good for beginners in this area as it allows you to play around with the different parameters to find out just what is needed to simulate moonbounce operation. A negative number indicates signals under the noise floor, and positive numbers indicate signals above the noise floor. The more positive, the better the chance of making the system work.

The program asks for simple data like the noise figure of your receive system (1.25 dB), receiver bandwidth (500 Hz), frequency in MHz (10368 MHz), Antenna 1 gain (10-foot dish = 45 dB gain, entered as 0.45), Antenna 2 gain (20 foot = 57 dB gain, entered as 0.57), and transmit power in watts (enter 28W, then let the program go). At the end you can select any one of the data points entered to re-calculate for custom designing. (If this sample data looks familiar it's because it's from the contact described above.) You can not only calculate its effects, but custom tailor the program for your special needs at other frequencies and station configurations as well.

This program is not new for me—it's something that I picked up in the early days of CPM and I found it on my old dinosaur computer (a Kaypro CPM machine from the early '80s). I take no credit for it and do not know the identity of the author or group who generated it. I'm just passing it along for your use. I have run this program on both CPM and IBM formats, using BASIC. This should

Notes from FN42

I had a great thrill on March 21! I had a chance to chat with Rick, Chief Op. for BY1QH and Ambassador to China, for about half an hour on 20 meters. Too bad the conditions were poor at the time, but there is always another day.

It's that time of year again for Field Day I plan to be actively involved with the KD1GJ effort in Keene, New Hampshire. I won't make it to Colorado for Field Day this year due to my teaching schedule for the summer.

Another story about hams, Silent Keys, and Field Day comes in a letter from P.J. and Ken Opfer, WB0MAL and WA0TOJ, friends from Gunnison, Colorado. P.J. relates a story about going to Fred and Fran Palmblad's house in Colorado Springs to take down a big beam antenna. Fred W0CYM became a Silent Key, and Fran said that the beam antenna should be put up on a hill somewhere where people could see it. The Gunnison Valley ARC felt that the beam should be put to use to honor Fred. They plan to use it during

their Field Day activities. Listen for the tribander on the air as W0GYV.

Have a great month and GET INVOLVED! 73, Amie, N1BAC.

Roundup

Anguilla Letter and Anguilla ARC Newsletter from John Rouse KA3DBN/VP2EBN: The newly elected officers of the Anguilla Amateur Radio Society (AARS) are: Dave Mann VP2EHF, President; Dorothea Mann VP2EE, Secretary/Treasurer; Larry Stott VP2EL, Government Liaison and Trustee for VP2EQ/VP2EA; Lou Bardfield VP2EB, Librarian; John Rouse KA3DBN/VP2EBN, Overseas Liaison and Awards Manager. DXers who operate from VP2E are encouraged to join AARS. For information contact KA3DBN at his Callbook address.

Generous donations from Angus Chassels (SWL) and Fritz VP2EY brought the cash needed to purchase a WACOM duplexer for the 2 meter repeater. By the time you read this it should be installed at the police communications facility with the "Super Station Master" located at the top of the 75-foot tower. Try it on 144.890 in/145.490 out (+600). A packet TNC set to the network mode and operating

on 145.010 MHz will operate at the same location providing island-wide connect capability for the VP2EA PBBS.

Jack Henry N6XQ has donated a turn-key 6 meter beacon to the AARS. Through the good graces of Terry Baxter N6CW/VP2ECW, Jack provided a modified Motorola radio with controller to give the world a Northern Caribbean area propagation beacon on 50.011 MHz. The beacon output is 50 watts; its callsign is VP2EA. [John Rouse KA3DBN, 2703 Bartlett Lane, Bowie MD 20715 USA.]

Chatham Island Downloaded from packet: A group of nine radio amateurs planned to be at the Chatham Islands from March 1 to March 9, 1993. They planned to operate under the callsign of ZL7AA. QSL information is ZL7AA, c/o P.O. Box 54, Hastings, New Zealand, or second choice, c/o ZL2AL at the Callbook address. Those who wish to QSL direct please send a self-addressed envelope with sufficient postage for return posting, otherwise all QSLs will be via the QSL bureaus in the respective countries. [Information forwarded by ZL2AMV @ ZL-BQK.#40.NZL.OC from details supplied by convener of the DX Group ZL2ARF, John Lane.]

Finnish Net/USA Downloaded from packet: The Suomi (Finnish) Net meets on approximately 7234 kHz, Monday, Wednesday, Friday, and Saturday at

10:30 a.m. EST. We welcome any Finnish-speaking hams to join us even if they don't have good linguistic abilities. It's lots of fun, and I'm sure you will enjoy it. 73 from Willie W8YNY, Crystal Falls, Michigan.

Honduras Downloaded from packet from Jorge Escotto HR2JAE @ W0XXK: If you have had contacts from HR stations without an answer, please send us your package certificate with the QSLs unanswered. Add an envelope for each one and do not forget the mail cost. Send to: U.R.E.H. Bureau, P.O. Box 73-73, San Pedro Sula, Honduras, C.A. Our bureau will contact those people and help them answer. If you have already sent IRCs or postage stamps, please advise us also. Many thanks from the Union de Radioaficionados Experimentadores de Honduras (UREH).

Japan From the JARL Newsletter: According to the IARU calendar, the Chinese Taipei Amateur Radio League (CTARL) joined the IARU as its 126th member as a result of voting by all IARU member societies.

CTARL was founded in 1991, and the number of its registered members at the time of application was 79. Mr. Tim Cheng BV2A/BV2B has been named president, and Mr. James Fang BV2BO director of its Secretariat. All correspondence may be addressed to CTARL, P.O. Box 93, Taipei, Taiwan.

Why buy a TNC?

PC HF FAX + PC SWL \$179.00

SPECIAL COMBINATION OFFER

For a limited time, if you order PC HF FAX \$99 (see our other ad in this issue), you can add our new and improved PC SWL 3.0 for \$80.00 instead of our regular low price of \$99.00.

PC SWL contains the hardware, software, instructions and frequency lists needed to allow you to receive a vast variety of digital broadcasts transmitted over shortwave radio. All you need is any IBM PC or compatible computer and an SSB shortwave receiver. The product consists of:

- Demodulator
- Digital Signal Processing Software
- 200 Page Tutorial Reference Manual
- World wide Utility Frequency List
- Tutorial Audio Cassette with Samples
- PC SWL automatically decodes Morse code RTTY, AMTOR, SITOR, NAVTEX and ASCII

PC SWL lets you tune in on world press services, meteorological broadcasts, ham radio operators, coastal shore stations, aviation telex and much more digital action on the shortwave bands. Why pay for another expensive box when a simple interface and your PC can do the job?

ADVANCED FEATURES:

- Tuning Oscilloscope
- Digital Waveform Presentations
- Auto Calibration and Code Recognition
- Continuously Tunable Filter Frequencies
- Variable Shift
- Adjustable CW Filter Sensitivity
- Unattended Capture and Printing
- Integrated Text Editor
- Integrated Log and Database
- Shell to DOS applications
- Seamless Integration with PC HF Facsimile

Call or write for our complete catalog of products. Visa & MasterCard welcome.

CIRCLE 39 ON READER SERVICE CARD

endar are May 30th, the 35th General Assembly; August 20-22, 1993 Amateur Radio Festival; and October 31, All-Japan ARDF Championship.

The JARL received a Fax from the Chinese Radio Sports Association (CRSA) saying: "Opening of individual amateur radio stations has been permitted and the first such stations are to operate from 10 o'clock, the morning of December 22, 1992. The prefixes of their call signs are BA, BD, and BG." The stations will be set up and operated by none other than individual amateur radio devotees and used solely for self-training, mutual communication, and technological studies. Those desiring to set up a station must obtain permission from a nearby Radio Station Control Committee. Additionally, they must obtain a radio station license before actually putting the station to use.

Mongolia Letter from T. Naranbaatar JT1BV: Greetings to you from Mongolia from the president of "Descendants of Chinggis Khan" International Radio Club. The club was set up in November 1992 to immortalize the memory of Chinggis Khan (king) and his successors during the Mongolian Empire. Anyone can join our club. The club call sign is JT1V. We are pleased to sponsor several awards: Chinggis's Chronicle; Ugedei's Chronicle; Hubilai's Chronicle. For further information, either for membership or the awards, please contact us: Descendants of

Chinggis Khan International Radio Club, P.O. Box 106, Ulaanbaatar 51, Mongolia, Central Asia; Telephone: 32-84-02, 56-0-32; TLX: 79264 BUFAM MH; Fax: 976-1-310060.

Mozambique Downloaded from packet from ZS5S @ K2PPH: As of March 7, 1993, new call signs came into use in Mozambique and now conform to the ITU standard. John, ex-C9RJ, now-C91J, reports the new call signs recently assigned: C91-C96 will be the normal calls with C97, 98, and 99 for possible special events. It was proposed that C99 be used as a sort of Novice call (VHF privileges only). It is still not clear, but provision will be made for visitor operators and they probably will be authorized to sign /91. John also reports that the Department of Telecommunications in Mozambique is sympathetic towards amateur radio and is very cooperative. Radio classes have started recently and there are seven enthusiastic participants. 73 de Joe ZS5S, Sysop Aplink S. Africa. [HURRAH!—Arnie]

Russia Downloaded from packet, NT2X and WB2DHY: Russia is considering new guidelines for visiting foreign amateurs. Under consideration are: 1) RV7 call sign series to be assigned to foreigners; 2) Exams to be passed; 3) New paperwork, application with request from a Russian sponsor; 4) Some sort of fee will be instituted, in hard currency, for the license. All this is

in the process of development and nothing is firm at this time. I'll try to find out more and pass it on. 73, Ed NT2X.

Russia/Ukraine/Lithuania/Bulgaria Downloaded from packet: The popularity of communications with the ex-republics of the former USSR has prompted this list of packet bulletin boards: UZ3AXO.#MGU.RUS.EU, Moscow State Univ.; RS3A.#MSK.RUS.EU, Kremlin, Moscow; RK3KP.#MSK.RUS.EU, Moscow; UA6LU.RUS.EU, Rostov; UA6LQ.RUS.EU, Rostov; UZ9CWW.RU.S.EU, Ekaterinoburg (Sverdlovsk); UZ9OWD.RUS.EU, Novosibirsk Tech. Univ.; UT4UX.UKR.EU, Kiev; UB5LMJ.UKR.EU, Kharkov; U5WF.UKR.EU; LY2WR.LIT.EU, Vilnius; LZ2XA.BUL.EU, Sofia. Many thanks to KA2JXI and UA3CR. If you know of other BBSs in the former USSR, please pass them on to Dick N1MDZ @ K1RQG.ME.USA. NA.

Switzerland From the International Telecommunication Union (ITU) Press Release: Three new members have joined the ITU since the beginning of the year: Georgia, 7 January; Slovakia, 23 February; Kazakhstan, 23 February. As of 23 February, there are 176 members of the ITU.

Brasil

Well! We are having troubles delivering DX QSLs to the IARU Bureaus and we hope you'll accept our reasons, giving us credit for trying, for we are all rowing in the same boat.

Since 1934, when LABRE, the Brazilian Radio Amateur League, was formed, we have had a separate branch in each of our 28 states, with the LABRE managing the QSL Bureau. But, little by little, the expenses have been making it impossible to be managed by LABRE alone. LABRE's statutes were modified in June 1992 to pass the responsibility for delivery of QSLs to each of the branch organizations, a sudden nightmare for almost all of them. Because of the increased expense, each branch was certainly not ready to face this problem.

We are having no problem receiving DX or Brazilian QSLs; it is the return that we are having problems with. We're working hard to find our way out, and I'm sure we will, but please be patient.

Seventy Centimetres Under the Gun On January 12th, 4X6ZH, the IARC repeater coordinator, dropped a bombshell on the weekly IARC net. Isaac stated that far-reaching changes

The ears have it!

“The R8 is like a breath of fresh air, with its ground-up engineering and up-to-date digital control from the front panel. I am very pleased to see a quality HF receiver of American manufacture that should successfully compete on the world market.”

Bill Clarke
73 Amateur Radio Today

When we introduced the American-made R8 Worldband Communications Receiver, we knew it would be judged by some very discerning ears, experts accustomed to the finest in short-wave listening equipment from around the world. After listening to the world on the Drake R8 loud and clear, they have delivered a decisive verdict.

They appreciated the R8's sensitivity, clarity, simplicity, and all-around versatility so much that many of them declared the R8 simply the best of its class. High praise, indeed, from very well-traveled ears.

But why take the word of mere

experts? Put the Drake R8 to the test yourself with a 15-day money-back trial period on factory direct purchases, and let your ears be the judge. If you're not impressed by Drake's quality, performance and ease of operation, all in a receiver costing less than \$1,000.00, return the R8

Receiver within 15 days, and we'll refund your money in full, less our original shipping charge. To order your R8 factory direct, for more information, or for the dealer nearest you, call **1-800-723-4639** today. We're confident that once you've listened to the R8, your ears will hear of nothing else.

R.L. Drake Company

CIRCLE 147 ON READER SERVICE CARD

are in the offing for our 430-440 MHz band (presently used on a shared basis, with amateur transmissions being on a secondary non-interfering basis). He said that we amateurs are in a STATE OF EMERGENCY insofar as 2 megahertz of the band are to be given away to the major two-way communications company in Israel for commercial use. Although there had been some vague rumors in the past, nothing had been stated publicly about the possibility of being dispossessed of some of our prime spectrum.

Although still under-used, with 2 metres fully occupied and all the Phase 3 and Microsat satellite activity utilizing 70 centimetres for up and downlinks, 430 MHz is prime real estate for near-future amateur activities, a very important part of our spectrum.

Then, just over a week later, the January IARC *HaGAL Magazine* appeared in our mailboxes. The published minutes of the September 13th (!) IARC Executive meeting let the cat out of the bag:

"Peleg (4X1GP) reports that the mobile communications (service) is in dire need of frequencies. The national frequencies committee (of the Ministry of Communications) appointed a sub-committee, and it recommended that 7 megahertz out of our UHF range be taken for the benefit of other elements. A sitting of the frequencies committee

in which Peleg was present turned down the recommendation and decided on the allocation of 2 megahertz for the mobile service and didn't state from where. The committee was instructed to hold a technical meeting to find a way to integrate the mobile service into the amateur allocation."

For years the Ministry had forbidden the hams to establish new repeaters on the 70 centimetre band. Activity has been mainly on the 438.650 Tel-Aviv and 438.800 MHz Haifa repeaters (input 7.6 MHz down), a few sparsely used simplex channels throughout the band, Ralph 4X1IF working moon-bounce and tropo on 432 MHz, and a smattering of satellite activity between 435 to 436 MHz by a handful of amateurs.

Now a sudden awakening has come, "Use It or Lose It," with plans for moving the old Tel-Aviv UHF machine down to Beersheva and a link for packet forwarding on 70 centimetres. The fact may well be that this is all too little and too late. There is a sense of outrage on the part of many hams and questions about what has been going on behind the scenes. On that same IARC Tuesday evening net when 4X6ZH "spilled the beans," one of our elected officials urged us not to discuss the matter on the air, but to wait for the IARC annual membership assembly on February 25th when all will be told. For

sure, there is now a vital issue at stake, and that get-together promises to be a hot one. [Does this sound familiar to the hams in the United States, the "taking" of 2 MHz of the 220-225 MHz band? Commercial interests, and money, talk! As Ron says "Use it, or lose it!" And there is no guarantee that even if we use it, we will not lose it.—Arnie]

OKINAWA JAPAN

David Cowhig J76CBQ/WA1LBP
AmCon Naha
FBU PSC 556, Box 840
FPO AP 96372-0840

In early November I made a short visit to Taipei (BV). The xiangchangzu "sausage tribe" of Taiwan now has grown from one to over 1,800 members over the last few years. Ham radio, personal radio, and a wide array of business radio services became available to the general public about three years ago when martial law ended. Who uses what frequency hasn't quite been settled yet. In one shop in the Pa Teh Lu electronic row an ICOM 2 meter handie was described as a CB radio and 144.800 MHz as the frequency used by motorists to exchange traffic information. In a second shop, a salesman said that businessmen buy ham equipment by day and hams buy it by night. In a third ham radio shop I met a self-described "underground ham" who talks with friends on 2 meters while he studies CW for the Taiwan ham examination. He told me that Taiwan has tens of thousands of unlicensed 2 meter operators. I see no trace of unlicensed operation on HF, though. All the BVs I have spoken to on HF from neighboring Okinawa are fine operators. Once Taiwan has adjusted to this revolution in radio availability, the number of licensed hams will certainly be far higher than it is today.

While in Taiwan I bought several issues of two Chinese language magazines which cover ham radio extensively. *Yeyu Wuxiandian* (CQ Amateur Radio Magazine), Shin Sheng Rd. Section 1, Lane 56 No. 12 fourth floor, Taipei, Taiwan, is published semi-monthly. The September 1992 issue discusses the Taiwan-Korea-Japan-Russia 430 MHz test in late July, the Taiwan 2 meter packet BBS network, the progress of the China Taipei Amateur Radio League founded March 1, 1992, the June 1992 annual amateur radio examination given in Kaohsiung (344 of 555 passed the exam), 10 pages of Japanese lessons for Chinese hams, Shane BV2FA's report on ham radio around the world, and an article by Lin Polung BV5AF on the WA7BML packet RBBS adapted for English and Chinese language packet radio in Taiwan.

The second magazine, 41-year-old *Wuxiandian Jie* [Electronics and Radio-TV Technic], Pa Teh Road Section 2, Lane 312, Number 19 Sixth Floor, Taipei, Taiwan, expanded its coverage to include ham radio. The November 1992 issue included ads for several

Taiwan brands of VHF and UHF handie-talkies such as Pro-Power and Union, a 200 watt output 2 meter amplifier with GaAs FET preamp from Aria, and several Taiwan-made ham antennas. Articles discussed radio propagation, antenna construction, frequency checking, how the Global Positioning System (GPS) automobile navigation systems work, setting up your first ham radio station, the Taiwan packet BBS network and its APLINK connection through BV5AF on 14.072 MHz LSB mark, basic transmitter principles, a four-page article about the radio-electronics inventors Russell and Sigurd Varian by Qing Shan, plus articles on SCR motor control, introduction to optoelectronics, railroad electronic monitoring and control systems, bar codes and bar code readers, digital image processing, remote control of PCs by telephone, a 10 mW QRP AM transmitter, and installments in series on elementary electronics and radio technology. This 160 NT (US \$6) magazine with its 150 pages of advertisements and 200 pages of articles reflects the robust good health of the Taiwan electronic industry and, incidentally, the role that ham radio now plays in Taiwan in training a new generation with a sophisticated knowledge of radio and electronics technology.

PEOPLE'S REPUBLIC OF CHINA

Rick Hunter, Chief Op BY1QH
Room 316, Building 25
Tsinghua University
Beijing 100084
People's Republic of China
Packet: BY1QH @ JA5TX.JPN.AS

More than 30 Chinese Amateur Radio Veterans spent a lovely day at BY1PK, the Headquarters of the China Radio Sport Association (CRSA), on January 20 in Beijing. Many of them were friends before 1949 and seeing each other again in this special place has turned out to be something quite exciting. Mr. Tong BZ1AA and Mr. Chen BZ1HAM were present on behalf of the CRSA.

TUARC has been honored by visits from many other hams. Some of those have been: Dieter DJ7BU, a German engineer at Siemens, with friends Meng BZ1FB and Ling BZ4ROM; Benny BV4HF, a 23-year-old medical student; Mr. Li Liang BY2SY and Miss Du Fan BY6NZ.

We have been very pleased with the response from many who have wished to exchange flags with us. We look forward to many more. We are now on the WARC bands using a Kenwood 440S and a ground plane vertical antenna. Sorry, CW on 12/17/30 meters is not available at this moment.

Our thanks to many who have sent us messages and talked with us on the air. Our continued thanks to those who pass this information on to the rest of the world via packet and magazines. What questions do you have? We would be glad to answer them for you.

ID-8 Automatic Morse Station Identifier

Compatible with Commercial, Public Safety, and Amateur Radio applications. Uses include Repeater Identifiers, Base Station Identifiers, Beacons, CW Memory Keyers, etc. Great for FCC ID Compliance.

- Miniature in size, 1.85" x 1.12" x 0.35"
- Totally RF immune.
- All connections made with micro-miniature plug and socket with color coded wires attached
- CMOS microprocessor for low voltage, low current operation: 6 to 20 VDC unregulated at time
- Low distortion, low impedance, adjustable sine wave output 0 to 4 volts peak to peak
- Crystal controlled for high accuracy
- Transmitter PTT output (to key transmitter while ID is being sent), is an open collector transistor that will handle 80 VDC at 300ma
- Field programmable with SUPPLIED keyboard
- Confirmation tone to indicate accepted parameter, plus tones to indicate programming error
- All programming is stored in a non-volatile EEPROM which may be altered at any time
- Message length over 200 characters long.
- Trigger ID with active high or low.
- Inhibit ID with active high or low. Will hold off ID until channel is clear of traffic.
- Generates repeater courtesy tone at end of user transmission if enabled.
- Double sided tape and mounting hardware supplied for quick mounting.
- Operating temperature range -30 degrees C to +65 degrees C
- Full one year warranty when returned to the factory for repair
- Immediate one day delivery.

Programmable Features

- Eight programmable selectable messages
- CW speed from 1 to 99 WPM
- ID interval timer from 1-99 minutes
- ID hold off timer from 0-99 seconds
- CW tone frequency from 100 Hz to 3000 Hz.
- Front porch delay interval from 0 to 9.9 seconds
- CW or MCW operation

\$89.95 each
programming keyboard included

give you some insight into just what is needed to pull off a moonbounce contact.

I hope you use this program to evaluate your typical station for moonbounce operations. It will give you a good idea of what is going on and will allow you to assemble your specific station requirements for successful operation.

Mailbox Comments

Ian Hunt of Bridgetown, Australia, questions the availability of the 10 MHz standards that I made available quite some time ago in this column. Ian, I am sorry to say that the oscillators were a bigger hit than I expected. They went fast and are now all gone. I even managed to pick up an "unheard-of" second bunch from the same surplus dealer who had the first; even these are gone. If I can find another bunch of 10 MHz oscillators of reasonable accuracy I will pick them up and let you know.

I wouldn't have even made the oscillators available if it hadn't been for Bill Brown WB8ELK—I just did not think that there would be any interest in them. However, Bill wanted high accuracy oscillators for an article covering modifications to a Heathkit frequency counter and had difficulty in locating them. Our connection was sheer accident. Too bad was not able to pick up a larger amount of the surplus oscillators. I'll

Continued from page 72

keep my eyes open and make you aware if anything shows up.

Joel K04AB inquired about the suitability of a Microwave Sensors, Inc. Model D8 microwave motion detector for 10 GHz operation (it uses a Microwave Associates MA86763 unit): "Is this unit suitable for 10 GHz operation, and do you know where I might find a surplus source for more of these units? Also, are the 30 MHz IF boards still available from you?"

Well, Joel, I haven't seen your particular unit but most of them on the market operate the same: power (DC) to the Gunn diode and connection of the detector diode to a suitable IF amplifier for receiving. All units are suitable for 10 GHz operation as they were intended for operation on 10,525 GHz for commercial operation. They usually have a frequency adjust screw allowing them to be re-adjusted into the amateur portion of the band. Also, the IF, a 30 MHz receiver PC board, is still available and the cost is still \$10 for the TDA-7000 and a PC board with a few parts tossed in. For a surplus source for microwave alarm units, check your local burglar alarm companies.

That's it for this month. As always, I will be glad to answer questions concerning VHF and microwave topics. Please send an SASE for a prompt reply. 73 Chuck WB6IGP.

SENSIBLE SOFTWARE SOLUTIONS

CopyCode from Sensible Software Solutions is a Morse code trainer for the Amiga computer that can be used to upgrade your amateur radio license. All controls—including frequency, volume, weight, character formation and transmission speeds, lesson length, and hide/show text—may be set by using a mouse. CopyCode contains all the characters on the FCC exam, and more. You can practice with the 14 predefined character groups or create your own groups using a unique on-screen keyboard. CopyCode contains thousands of random but repeatable sequences of characters, words, Q-signals, CW abbreviations and QSOs. You can also run multiple copies of CopyCode to practice receiving CW through QRM.

CopyCode is priced at \$23. For more information, contact *Sensible Software Solutions*, 4951-D Clairemont Square, Suite 262, San Diego CA 92117-2798; (619) 452-1938. Or circle Reader Service No. 202.

NCG/COMET

The COMET Model CX-333 Triband Base/Repeater Antenna, covering the 2m/220/440 MHz bands, is now available from amateur radio dealers nationwide. The CX-333 is a two-piece white Fiberglass antenna with an ABS screw-together connecting joint and compression washer for complete waterproofing and easy assembly. The overall length is 10'4", with a gold-plated SO-239 connector.

COMET's exclusive SLC (Super Linear Converter) design is used to produce excellent gain of 6.5/7.8/9.0 dB. The SLC means that the internal element is arranged in a vertical coil,

rather than a spring-type coil. This design produces higher gain and a pattern with a low angle of radiation. Additionally, each piece making up the element is soldered to the next, avoiding connections that could vibrate loose, or where corrosion could develop to attenuate the signal. As with all COMET antennas, it is completely pre-tuned and includes all mounting hardware.

For the price and more information, contact *NCG*, 1275 North Grove St., Anaheim CA 92806; (714) 630-4541, (800) 962-2611, Fax: (714) 630-7024. Or circle Reader Service No. 203.

THE GRAPEVINE GROUP

your problem in seconds. A very high percentage of Amiga problems are readily fixed by simple substitution of integrated circuits (ICs) in existing plug-in sockets. The novice, as well as the experienced technician, will find it simple to use. No other tools or equipment are needed.

The Amiga Troubleshooter is priced at \$12.95. For more information, contact *The Grapevine Group Inc.*, 3 Chestnut Street, Suffern NY 10901; (914)-357-2424, (800) 292-7445, Fax: (914) 357-6243. Or circle Reader Service No. 201.

NEVER SAY DIE

Continued from page 4

repair. It doesn't take much to screw up the DNA replication process, which is going on constantly as new cells are built and old ones phased out. The sharp wave fronts of CW square waves, which go from a few hertz on up into the microwaves, can't improve how our cells replicate and could help explain why hams have about double the deaths due to cancer as the general public. It might be worthwhile to find out if hams are any more susceptible to long-range illnesses than other people. When you mess up cells, you don't know what's going to break down. It could be more than cancer.

If you have a need for a reference guide to the published research papers in this field there are 21 pages of references on the 73 BBS . . . so far.

Cellular radios and cancer? I'll be amazed if there isn't a connection.

Me? A Bore?

Forsooth! Well, I can be when faced with a contact with someone who just refuses to talk. Is it residual mike fright which has persisted for decades? Some of these non-talkers have some fairly old call signs. Is it that they've never done anything? Never read anything much? Never gone anywhere? Never really thought? No, I'm sure that if I could sit down with them I could pry some interesting stories out of them.

Many of the DX ops I talk with are bitterly critical of American operators. All Americans seem to want is a QSL card! Many American ops seem to have had their contact formula spiels frozen at around the time of their first contact. Well, it's a lot easier than having to think. Thinking, apparently, is hard work. Well, I suppose so. It's something which is battered out of us in school, where a thinking student is a teacher's worst nightmare. It's almost impossible to beat a habit mercilessly pounded into us over 16 years of school.

Our whole society is built around not having to think. TV provides us with endless semi-entertainment that seldom demands any actual thinking. Movies are geared to entertainment, not thinking. Most business is routine and thinking is punished when it interrupts the routine. Talk with friends is mostly blather, with no sign of thinking involved. Gossip. The reason *US* and *People* magazines were started is because too few people could cope with *Time* and *Newsweek*. The news magazines tended to call for some thinking, something Donahue, Oprah, and *US* don't.

A Cultural Straitjacket

The wonder is that a few American hams have managed to break free of this educationally and culturally built straitjacket and are able to conduct interesting, intelligent conversations over the air. The one-way nature of our contacts which, despite improvements in communications technology, we fiercely refuse to drop, makes it much more difficult to talk than a normal two-way

QSL of the Month

To enter your QSL, mail it in an envelope to 73, Wayne Green Inc., 70 Route 202-N, Peterborough, NH 03458. Attn: QSL of the Month. Winners receive a one-year subscription (or extension) to 73. Entries not in envelopes cannot be accepted.

conversation. I sure hope a few hams will start working on some practical duplex systems so we can make talking easier.

We can do this via frequency separation, so we can both transmit at the same time, or we might do it via time splitting, where we share a frequency but send sound samples several thousand times a second. This would allow us to have as many as six or seven people all talking on the same frequency at the same time to each other, with everyone hearing the others.

In the meanwhile, if those of us who are looking for more than a QSL card out of a contact can make a serious effort to get others to actually talk, perhaps in another generation we'll begin to see some results. We might establish some special frequencies for actual non-QSL contacts. Do you think there is any potential for conversational nets?

started pushing for a no-code license a few years ago and how amateur radio has gone to hell in a handbasket as a result of this accursed new license. Tell 'em how repeaters have screwed up hamming and I never should have promoted 'em back in 1969.

If you're short of mud to throw at me, I'll be glad to wet down your adobe hacienda so you can have more ammunition. Half of you will absolutely hate my pro-choice thoughts. The religiously overwrought will go bananas over my ideas on religion and have enough to talk about to keep them going for a generation. But hey, you've never asked me about God, Christ, Mohammed, Sri Krishna, Smith, Moroni, and Amee Semple McPherson. There are whole new fields of controversy to blow out of proportion.

We aren't short of groups looking for fights. There's feminism, homo-ism,

sions I have. This usually brings another letter telling me how stupid and opinionated I am. Sure, I'm opinionated, but at least I've done a lot of homework before arriving at my opinions.

Using Edison's definition of genius, mine is 99% perspiration and 1% inspiration. But you know, after the 99% perspiration, that little 1% of inspiration is very exciting and makes the perspiration more than worthwhile. So I keep buying books which are recommended as being worthwhile and reading them, highlighter always at hand. I keep a growing clip file of ideas from magazines. I find the most interesting people I can to discuss ideas. I'd love to run into you on 10, 15, or 20m and find out what you've done that we can talk about. But if all you're after is a crummy New Hampshire QSL you can go jump in a lake.

You probably aren't going to run into me during contests. I've done contests. I've done all the contests. I've worked all the countries I ever want to work, so I don't need any more QSLs. I've thrown out more certificates than 99% of you have collected, so I don't need any more certificates. No, when it comes to hamming, I mostly like to have conversations.

Oh, it's fun to make contacts via the satellites, even though some of them don't support long conversations. But having done that and earned a bushel of QSLs in the process, I don't seem to find myself driven to get my station set up again for OSCAR.

Satellite contacts are something I recommend everyone try. But the contacts tend to be more like a contest and after awhile the fun wears thin. Few of us other than true-blue DXers enjoy an endless contest.

Heck, after DXing from over 50 countries, I don't seem to be as interested in working the pile-ups from rare spots as I used to. Oh, that was tons of fun and I'll never forget one minute of any of my trips. But I've done that, and don't seem to be as readily volunteering for the hardship duty that goes with many DX-peditions. Besides, it's time I got you to get out there and have the fun.

Maybe you can practice up a bit before we make a contact. Maybe you can try to break that habit of not actually talking over the air. How about trying some contacts where you do not mention your equipment . . . not even your antenna. Keep your signal report to just readability. I do want to be sure you can hear me when we're talking. I'll bet you'll find this a serious strain on your ingenuity at first.

Remember, the more you get the other chap to talk, the more interesting the contact is going to be for him. He'll never notice that you aren't talking much, but are mainly asking him questions about him. All he'll know is that he's had more fun during this contact than he's had in ages.

However, when we contact you should do most of the talking. Remember, I've been sharing my joys and disappointments with you via my editorials, so now it's your turn to tell me about you.

"This usually brings a letter telling me how stupid and opinionated I am."

I'm not sure what the benefit is of nets where dozens to hundreds of ops check in to the net control and report they have no traffic. You can't talk with dozens of people. Oh, you can lecture them, but that isn't talking. Nets have the benefit of convincing thousands of hams that they're doing something. The upside of nets is that at least they seldom require anyone to think.

So? So what can you talk about? Well, if nothing else you might ask 'em if they've read the latest baloney in my editorials. I cover all sorts of topics, so you can rip me apart on about almost anything. You are always telling me that you don't agree with everything I write. Okay, put your big mouth where your pen is and tell the next chap you are in contact with what you disagree with and why. Tell 'em what you think of Wayne's pontifications.

I'm Stupid and Ignorant

Tell 'em you think I'm stupid and ignorant for suggesting that our public schools are destroying our kid's minds. Tell 'em what a lousy thing I did when I

cripple-ism, a wide range of religious fundamentalisms, a few political-isms. Oh yes, racism. So if we can't have intelligent conversations over the air, perhaps we can at least vent our bigotries and non-thinking prejudices, perhaps building up more steam than we can let off.

The upside of this is that when people get angry they louse up their immune system and are open to all sorts of both long- and short-range illnesses. Short-tempered people tend to be sicker and shorter-lived, so we don't have to deal with them for as long.

When you run into an angry, sarcastic person over the air you can sign off and change frequencies. But pity his family and business acquaintances who have to live with this poison! I get letters from angry people. Not many, but a few. That's natural because I write what I think . . . always with the proviso that if you disagree I want to hear why you disagree. Angry people don't have any whys, just vehemence. I often waste my time trying to answer their angry letters, explaining why I've come to the conclu-

RAI ENTERPRISES

"Quickyagi" from RAI Enterprises is an inexpensive and easy-to-use yagi modeling/optimizing program that is both fast and accurate, and is used by antenna manufacturers, universities, government agencies and amateurs worldwide. "Quickyagi" utilizes a highly intuitive user interface with fully prompted functions, single key stroke menus, and scrolling highlight data access. Designed for nontechnical as well as technical users, it utilizes a unique auto-design function. The user only needs to input the desired frequency of operation, the number of directors, and the element diameter(s), and the program will automatically de-

sign and optimize a yagi, with a choice of optimum F/B ratio or optimum gain at the selected front-to-back ratio, while attempting to maintain minimum side-lobe levels. Other options include a bandwidth optimizer with a choice of wide or minimum frequency bandpass and pattern bandwidths. The auto-optimizing function may be used separately to optimize existing yagi designs.

"Quickyagi 2.5" is priced at \$37, plus shipping and handling. For more information, contact **RAI Enterprises**, 4508 North 48th Drive, Phoenix AZ 85031; (602) 848-9755. Or circle Reader Service No. 205.

POLYPHASE CORPORATION

The second edition of *The "Grounds" for Lightning & EMP Protection* is now available from PolyPhaser Corporation. This expanded and updated edition contains 100 pages of information detailing the proper techniques for grounding and the protection of electronic equipment from the destructive energy of lightning and nuclear EMP. The publication's primary focus is on protecting radio communications equipment.

Other in-depth protection topics covered are: telephone, central office equipment, computers, local area networks, cable TV, TVRO, and security cameras.

This how-to-do-it publication is priced at \$22.95. For more information, contact **PolyPhaser Corporation**, Customer Service Department, P.O. Box 9000, Minden NV 89423-9000; (702) 782-2511. Or circle Reader Service No. 204.

FLYTECRAFT

FLYTECRAFT has introduced two new antenna models, the Model CFN and the SFX line. The Model CFN (left) is a 16-element, wideband VHF/UHF antenna designed for amateur radio operators or scanner enthusiasts, and for all frequencies from 50 through 1300 MHz. It provides a solid low angle of radiation or reception with a low SWR across the spectrum (less than 1.7 to 1 with unity gain). The Model CFN is designed for both indoor and outdoor use, and for permanent or portable use (to assemble, you simply insert the elements and tighten the screws).

The SFX line of monoband vertical

antennas (right) comes in five different versions for 40, 30, 20, 15 and 10 meters. These antennas are only nine feet high (the 10 meter model is seven feet) and are designed to sit on a patio, lawn or balcony. They can be set up or taken down in just a couple of minutes, and they are unobtrusive enough for antenna-restricted locations.

The CFN is \$119.95 (plus \$5.50 S&H); the SFX 40, 30, 20 and 15 are \$99.95 each and the SFX 10 is \$89.95 (plus \$6.50 S&H per antenna). For more information, contact **FLYTECRAFT, P.O. Box 3141, Simi Valley CA 93093**; (805) 583-8173, (800) 456-1273. Or circle Reader Service No. 206.

Why We Were Not at Dayton

As I write this, the Dayton Hamvention is a week ahead. When you read this, the Hamvention will be six weeks in the past. (Kinda' like time travel, isn't it?) I can assume that there are several thousand of you who took note that, for the first time in almost 30 years, 73 did not have a booth at Dayton. Wayne and I were both there—Wayne to give his annual forum, me to walk around and bother people—but we did not have a display booth as we've always had.

I hope those who renew their subscriptions at Dayton every year were able to find one of the several thousand fliers we printed, offering the same deal that we would have offered in person. (If not, just send your Hamvention ticket stub, along with your renewal and \$15, to: 73 Amateur Radio Today/Dayton Subscription, 70 Route 202 North, Peterborough NH 03458. Do not send it to the regular renewal address.)

Many of you are probably curious as to why we decided to bypass Dayton this year. There are two main reasons.

Reason #1

We do not go to hamfests to make a direct profit. In fact, if you look at what it costs to attend a show, compared to the actual dollars we take in, you'd think that we lose a lot of money at every show we attend. Added to the cost of booth rental, air fare, hotel and meals, is the hidden cost of lost revenue. 73 is a pretty tight ship. We don't have enough staff to send to as many hamfests as we'd like. When I'm traveling to and from a hamfest, I'm not in the office and that can cost the company money in lost productivity. Even more important, every day that an ad sales rep is not in the office is a day of lost sales. I wish I could hire a few people to do nothing but travel to a different hamfest every weekend, but I can't.

Every day spent out of the office is a trade-off. Where the money spent on hamfests does pay off is in advertising dollars and public relations. Just being at the show puts us in front of subscribers and potential subscribers. This is good PR. Where the big money comes in is in advertising revenue. Hamfests are an opportunity to get face-to-face with our advertisers—to thank the ones who are regular advertisers, and to build a relationship with those who aren't, in the hopes that they someday will become advertising clients. We spend a lot of time on the floor of the convention, just saying "Hi" to our advertisers (and non-advertisers). We also work after the hamfest closes its doors for the night, going to dinner with potential advertisers, working out special promotions, or just socializing. Working a hamfest is usually at least a 12-hour day (and most of that is on your feet), but it pays off. Signing a single advertiser to a 12-month contract for a single page pays for the expenses of attending five hamfests.

The problem with Dayton is that it is so big that we don't get to spend any time with our advertisers. It is so

crowded that we don't have a chance to really talk to those who stop by the booth. All we can do is take their money and then say, "Next, please."

Dayton is so expensive to attend that there is no way we can make back the cost. Even though we sell at least 10 times the number of subscriptions we sell at any other hamfest, that revenue doesn't even come close to offsetting the enormous expense of attending. For what it costs to attend the Dayton Hamvention, I can attend five or six other shows, which is a much smarter way to spend an already tight budget.

Reason #2

The other reason we finally stopped throwing money down the Dayton hole is that the Hamvention is, in my not-so-humble opinion (as well as the opinions of many members of the amateur radio business community), the absolute worst-run hamfest of the year. Somewhere along the line, the Dayton Hamvention became a business—a big business—and yet it is still managed as if it were a local club event.

The price of a booth at Dayton is over twice the price of a booth at most major hamfests. What do you get for this overly-inflated price? Not much! You get to wait around for hours while the contents of your booth are delivered. You get to pay extra for such basics as a table skirt. You get to spend hours hunting down someone who can answer the most basic of questions. You get to spend the night at a hotel that is probably at least a 30-minute drive from the convention. You get to spend three days in a dirty, smelly and hot building that is nowhere near large enough to hold the number of attendees and exhibitors (every year I wonder where Dayton's fire marshal is). You get to pay extra to staff your booth with enough people to properly run it. You get to wait again on Sunday for the contents of your booth to be "checked-in" before you can leave. In short, after putting over a thousand dollars into the Hamvention coffers (and thousands more into the local economy), you get treated like your business isn't important. The attitude is, "We don't care if you're here or not, because we'll still make gobs of money without your business."

Spending of money, I've often wondered where all that money goes. There are 657 exhibitor spaces at Dayton. Each one of those spaces costs at least \$425. For some strange reason, Dayton is the only place I know of where a second booth space costs more than the first. For the sake of simplicity, let's say every booth sold for the single booth price. That's \$279,225 just for the inside booths. There are roughly 4,350 flea market spaces, each selling for between \$30 and \$50 each. Let's split the difference and say the average space goes for \$40. That's another \$174,000. Each one of those spaces has at least one person, and that's an additional \$11 each. Add another \$47,850. Paid attendance has been over 30,000 for several years, but let's use that as a

Jim Gray W1XU

Jim Gray W1XU
210 East Chateau Circle
Payson AZ 85541

The HF bands this month are expected to provide a mixed bag of conditions. The summer solstice occurs while the sunspots continue their steady decline, as evidenced by the Solar Flux data given by WWV at 18 minutes past each hour.

You may expect the best days (G) on the 5th, 10th, 18th, and 30th . . . give or take a day or two. The worst days (VP) are likely to occur on the days from the 21st to the 27th, when conditions are very likely to be violently disturbed with active to storm conditions taking place in earth's magnetic field. Signal absorption levels are likely to be very high and DX poor to nonexistent. A full eclipse of the moon will occur on June 4th.

During the period between the 21st and 27th you may also expect some violent weather and other geophysical phenomena. Be aware of the possibility of a hurricane about that time. There may also be some possible earthquakes and volcanic eruptions around those dates. Although such a report is speculative in the extreme, keep a sharp lookout and let me know what you experience at your location. The first day of June is also likely to be very poor (VP) to poor (P), but conditions will rapidly improve.

On Good days and even Fair days you will find 10 and 12 meters opening out to 1,000-1,500 miles, with very high signal strengths and rapid fades, due to sporadic E-layer ionization. On 15 and 17 meters, you will find trans-equatorial DX on Good days with occasional openings on east-west paths peaking during the afternoon hours at your location. Remember, DX travels westward with the sun. The 20 meter band is likely to be the best DX band during June, with strong conditions on Good days to most parts of the world. Early morning and late afternoon hours are particularly favorable for DX, and you can expect short skip to be strong out to 500 miles or so during the daylight hours. The 30 and 40 meter bands will give

you excellent DX opportunities during the evening, nighttime and early morning hours on Good days, subject to thunderstorm QRN (which certainly can dampen your enthusiasm). Short skip will also be good on this band, often as far as 2,000 miles at night. Midnight DX to Europe and dawn DX to the Orient can be expected on good days. In general, 160 and 80 meters are not considered to be good bands during daylight hours due to excessive absorption of signals. Occasional DX openings may be encountered on particularly favorable nights, peaking toward sunrise, but high noise levels will tend to be discouraging in the presence of strong weather fronts (see Poor and Very Poor days).

Predictions and forecasts are both an art and a science, so your scribe can be very wrong or very right on occasion, but I'm generally "on the money," so please let me know how these forecasts work for you. See you next month . . . W1XU

Contract: The act of reading this contract proves that you have extraordinary curiosity, creativity and intelligence. Therefore, you are hereby legally bound and ordered to select a project and build it, or design one and write an article for 73. If that's too tough, why not try one of the easy-to-build kits offered by our advertisers and then write us a review?

NEVER SAY DIE

Wayne Green W2NSD/1

Eureka! I've Got It!

Unless your short-term memory system has been short-circuited by Alzheimer's, you should recall my grouching about the road blocks our stupid simplex communications system presents to those few of us interested in even attempting to talk about more than the weather or an endless recitation of our rig model and serial number.

Simplex . . . where we have to talk one at a time. Where the other chap prattles on endlessly, repeating everything three times . . . only "everything" turns out to be more like nothing. And where there's no way to break in and tell him "enough already." Or even interject an "uh-huh" now and then. Well, we'd sure save a bundle on telephone calls if they worked that way.

Duplex . . . where a person can enter into an actual conversation. It's no wonder we hams tend to talk about nothing over the air. We start out in life learning to talk using two-way instantaneous communications. We even have the advantage of being able to see the other person, which makes the use of hand gestures and body language enter into the communication process.

There was an entertaining squib on one of the recent TV magazine shows showing people animatedly talking on telephones in street phone booths. There was a great waving of hands and even arms as they talked.

Well, it's going to be awhile before we're able to organize duplex ham TV, bandwidth limitations being what they are, but I've thought of a way we can quickly get going with duplex contacts on our HF bands. Imagine being able to hold an actual conversation with a DX operator on 15 or 20m!

It's those contoured showers that do it to me. As I say, I've been grouching about this situation, asking you for a solution. So, there I was in Dayton, on the morning of the opening of the Hamvention, taking a shower. Bam! It hit me! Of course, the answer is simple.

Most of my really ingenious ideas come to me in the shower. My employees cringe when I come in to work and say, "Hey, while I was taking a shower this morning . . ." They know this probably means we're about to start a new business. Eyes roll. A lot of other

people have written about the same phenomenon. It apparently has something to do with negative ions. They have a positive effect. I've thought about putting in a negative ion generator, but one shower a day is all my employees can handle.

The problem we need to solve with simplex operation is the blocking of our receivers by our transmitter. No, we don't have to design new receivers which can unblock in a microsecond, we can do just fine with the receivers we're using right now. And no, I'm not talking about transmitting on one end of the band and listening on the other. For most of us that would still zap our receivers. Crossband? Well, almost. Now, if you'll stop trying to second-guess me and let me explain . . .

One easy way to be able to listen on your own frequency while you're transmitting is to separate your transmitter and receiver by a mile or two. Did that light up anything for you, or do I have to go into the detail? Let's pretend that you have a ham friend a couple miles away. It could happen. And let's just imagine that you might be able to work out a deal with him so that the two of you could operate at different times and use each other's rigs. All you need is either a telephone link, which isn't expensive, or a UHF link, which also isn't expensive. My choice would be 10 GHz for the link. We've got 500 megahertz up there sitting totally unused . . . a sure recipe for its loss, if the FCC ever gets short of frequencies.

10 GHz transmitters are a cinch to make. And all it takes is about a tenth watt to work anywhere you can see. A few years back WA1KPS knocked together a pair of 10 GHz transceivers in boxes about half the size of a half-gallon milk carton. The antenna was a small horn coming out one side. With these we racked up a seven-state contact record. I worked him in seven different states and Chuck worked New Hampshire seven times.

With a radio or telephone link we can "ventriloquize" our voices by a mile or five and thus be able to listen on our own frequency while we talk. Or any other frequency, if we want to work split-channel. Of course, if you both want to operate at the same time then you'll have to go back to simplex

until the urge passes. I'll bet that once you get used to duplex, going back to simplex will be worse than watching TV on a small black and white set with a rabbit-ear antenna.

Yes, I know . . . both ends of any contacts will have to be set up with remote transmitting to make this work. So, we'll have to start setting up some special frequencies for duplex pioneers to meet. I'm open for suggestions. 14.313? Sure, why not. No one is using that frequency right now. It's about time we put it to constructive use. We could start in the 14,300-14,320 kHz part of the band and gradually expand. When SSB first got going it was started at the top end of 20m and gradually moved on down the band, squeezing out AM until it was all gone.

We're already seeing some sophisticated devices for remotely tuning our transmitters and even swinging our beams. If we can get duplex into action we'll see a lot more of these magically appearing in our ad pages as entrepreneurs get into the business. Eventually we'll start seeing remote control circuits built into our transceivers.

You say this must be illegal? Go soak your head! With sideband we have no carrier, so when we're listening we're not transmitting. This is perfectly legal.

Please let me know when you get set up for duplex so I can pass along the news in 73, thus encouraging others to get off their fat butts and get set up so they can talk with you.

The downside of all this is that after all these years of having never said anything of significance during a contact, are you going to be able to actually talk with people? Can you hack that? This may take some getting used to.

Remotely controlling the rig is a snap. Over 20 years ago I hooked up a spare Standard Radio 2m repeater to my 20m rig so I could operate it from anywhere in town. I was into morning mountain climbs up Pack Monadnock mountain, so I'd take along my little HT and talk with 20m ops all around the world while I got my daily exercise. It sure took the boredom out of the walk. Then I took the repeater over and set it up in Amman as JY73 . . . and left it there, along with

a suitcase full of HTs. I remember saying good-bye to King Hussein via the repeater as I was boarding the plane heading for Cairo and then home.

So, once freed from the tyranny of simplex, what are you going to talk about? Your rig? The weather? Cocktail party chit-chat? Can you stick to something you actually know about or are you going to get off into deep water with things where you have to substitute intuition and belief for thought? There's a lot of that going around.

The Biggest Change Since Repeaters

It's about time we got something new going. In the late '50s we got going with sideband. In 1969 we started with repeaters, which by 1973 became the largest activity in the hobby. In the 1980s we got interested in packet, but this hasn't been the grabber we had with sideband and repeaters. Perhaps in the '90s we can make duplex our new pioneering effort.

I can see clubs setting up HF transmitters at their repeater sites so club members can access the system and take advantage of the site and the distance from their home operating position. I've got a great hamshack location in Hancock (NH), complete with a tower and beam. I'd love to get it set up so anyone able to access the W2NSD/1 repeater could use this as a remote transmitter. I even have a repeater all set up we could use for the project. With some of today's rigs we should be able to remotely change bands, tune any frequency, and swing the beam. We might even figure out how to allow several ops to use it simultaneously so three or four could chat with South Africa just like they were all in the same room.

If you like the idea and try it out, this is an invitation to write about it. I'd like to see articles on control systems and reviews of any applicable commercial products. 73 helped sideband grow in the '60s. It helped repeaters grow in the '70s. We even helped packet in the '80s. Can we do it again with duplex? I think this could be the greatest thing that ever happened to amateur radio.

If any manufacturers are interested in working with us on this project I'd like to hear from them. Once we have something going I'll be devoting a good deal of space in 73 to the project. This will also give us something exciting to tell the general public. Yes, I'll be doing videos and getting them on TV stations wherever possible.

If we're going to keep our bands we've got to do a whole lot more than we've been doing to hold our franchise. We need to figure out how to attract youngsters by the millions, not by the dozens. We need to sell amateur radio and school radio clubs as a way for America to build the high-tech work force it must have to compete in the world of 2000 and 2020. The last thing we need is some 2020 hindsight telling us what we should have done in the 90s.

Continued on page 86

From the Hamshack

Greg Smith N8PPZ, West Carrollton OH Wayne, thank you for getting me up off my duff and upgrading. Thanks to you I finally passed the 5 wpm code test after taking it several times and failing because I procrastinated and did not really spend enough time studying. It's your fault that I am now a General, that I just couldn't stop, and I blame you, sir, for the fact that I am now trying to pound the Advanced theory into my head. Before I insult you too much, I just want you to know that I now see a reason to go on and get my Extra Class: because I WANT TO! Maybe I am foolish to think that the conversations on the lower bands are more interesting than they are on 10 meters and VHF. I am tired of an endless string of signal reports and 2 meter drivel. I guess it is too much to hope for (call me a dreamer), but I'll probably call you every name in the book if I find out that all other hams want are signal reports and QTH.

On a happier note, I did write to you before and what you wrote back caused me to do the above and more. I have now founded the Sinclair Community College club, and it is going well. I got a promotion at work, and in addition to operating a three-camera robotic studio camera system I am doing news writing and some assignment desk duties.

Last year at Dayton I talked with you and mentioned an idea about a new business. I guess I spoke too loudly because somebody else used my idea and started VIDEO ELMER. I lost out, dangnab! I had to think of something else, and I did. I sent out on the national ham radio echo on Relaynet a series of essays I called "How To Fix a Nation." These contained my ideas for fixing our miserable schools and ending the problem of teen violence. Unfortunately, I found out just how much other people think about these problems. People are too status quo and passive. I guess they just need somebody to give them a swift kick in the right direction.

Jeff Carter KK6RY, Simi Valley CA I agree wholeheartedly with you concerning the public school situation. I might also add that I agree with your attitude concerning the ARRL. I am a past member who opted not to renew. I decided to do this for a couple of reasons: one, the whole no-code fiasco; and two, the fact that I do not believe we are being represented in the most efficient way in Washington, DC, by the powers that be. If the ARRL is supposed to be our "mouthpiece" in FCC affairs and all the other political rot that goes on at Capitol Hill, then they are utter failures . . . If

we are to save frequencies from further degradation to commercial interests, we must put the technical-minded nature of the hobby back in the forefront and stop this selling out to the "big gun" commercial interest groups and others with their fingers in the spectrum pie. Next time there is an earthquake, fire or flood of disastrous proportions, let the dummies call UPS, their tow truck company, or any other VHF and above user for help! I think you get my drift.

As a VE, I have also seen the mess with the licensing system. I have turned in my badge, cut in two, and told the ARRL to stuff it. With the no-code situation thus promoted, all we have accomplished is a mass flooding of the system with a bunch of handle-talkie-wielding appliance operators. Sorry Wayne, I don't buy it! This strength in numbers jazz just doesn't cut it for me. Yea, I know, technology marches on and all that stuff . . . but I, being an ex-USCG radio man in the '70s, well realized the value of CW for daily and emergency communications. I don't like the "slighting" I see of this mode of communication. I am an avid QRP nut and also a member of the Society of Wireless Pioneers and believe in the preservation of CW and older radio history. Let the no-coders run the local bicycle races and show off with their \$500 handle-talkies. I'm not impressed. I'll stick to my 2 watt CW rigs, which I built myself, and take pride in my operating practices. To each his own, they say, but I don't care if I ever get on an FM repeater again. The trashing of VHF/UHF will end up ruining it for us all.

Dan R. Cation WB0SHN, Savonburg KS Wayne, I am writing in response to two letters that recently appeared in 73 Magazine. Both mentioned traffic radar and the allegations that its use may cause cancer. I would like to take exception to the first letter from Mr. Beegan in the February 1993 issue and to your personal comment that appeared following Mr. Mayer's letter in the April 1993 issue stating that " . . . there is plenty of evidence (facts) that prolonged use can cause serious problems for officers . . ." I would also like to thank Mr. Mayer for his comments.

First of all, to set the records straight concerning the lawsuits mentioned by Mr. Beegan, out of 13 lawsuits filed against Kustom Signals, nine have been dismissed for various reasons before ever even getting to court. One has made it to court and I'm sure that the plaintiff would have liked to speak to you before going to court . . . they lost . . . by the unanimous verdict of eight jurors, after about three hours of deliberation.

Just to let you know where I'm coming from, I am not a self-proclaimed microwave expert or anything like that. What I am is one of the proud employees of Kustom Signals, who has worked for them for over 18 years. No, I don't work on the radar products. I am not a member of management or an engineer. I am currently an engineering technician and have worked as a technician somewhere in the plant for those 18-plus years. You would think that if one officer using one radar a few hours a day could cause cancer, then the technicians who test these radar units (currently around 25 units a day, nine to 10 hours a day, four to five days a week) would see some ill effects. I personally know one technician who has been doing just this . . . for close to 20 years! Kustom is very proud that it has many long-term employees who, like myself, have been sitting around in this steel building in Chanute, Kansas, for 10, 12, 15, 18, and even 20 years and longer with these "KILLER" microwaves bouncing around us. Guess what? There hasn't been one case of cancer or any other strange unexplained illness in any of Kustom's employees.

We are a small, privately-owned company of a little over 100 employees. We are not some corporate giant. These lawsuits nearly cost us all our jobs, in an area where there are very few jobs available. They did cost some of our co-workers their jobs (in a layoff) and caused the company to take such belt-tightening measures as going to a four-day work week just to keep the company going and to be able to defend ourselves against these allegations. We still have at least two more lawsuits to defend ourselves against. I would like to know where these "facts" that you speak of are. We sure haven't seen any from any reputable sources yet. By the way, I haven't seen any melted hood ornaments or dead birds from our radar, either. And, as one of our co-workers who recently retired (in good health) put it: Hell No, We Don't Glow!

Thanks to Mr. Mayer for his realistic point of view.

Dan—Thanks for your letter . . . I can understand your concern.

If successful lawsuits were a measure of dangers, that would be positive proof that cigarettes pose no danger to health. The asbestos industry fought the same battle for years . . . successfully. Now the power companies are also fighting the same battle against scientific research.

I don't doubt that you haven't seen any proof. But then I doubt that you have made any effort to look. Have you accessed the 73 BBS yet and gotten a download of a list of the scientific papers in this field? The list is over 20 pages long and growing every week. I just got in a new stack an inch high from the leading researchers.

The damage these fields are doing is insidious. There are a few exam-

ples of the extremes, but the research scientists are just beginning to understand the lower level effects. How much do you know or have you tried to learn about how the cells of your body function and communicate? And what happens to you when this communication is interfered with by a radio or magnetic field?

Have you seen any of the videos of police officers who have gotten repeated brain tumors right in the area where their radar antenna has been blasting their heads? Now we're starting to see the same thing happening with cellular telephones which are operated close to the head. But do you really think that a field which can do that to heavy users isn't doing anything at all to lighter users?

Not that I have much compassion for traffic radar manufacturers. Have you any research reports which show that the use of traffic radar significantly saves lives? There are endless reports showing that police radar is a major source of funding for towns, but that seems to be its use. Most accidents happen at low speeds. Higher speed accidents tend to involve alcohol.

Studies show that, lacking speed limits, people tend to drive at the speeds they are most comfortable with and thus the accident rate is lower than when speed limits are imposed. The research reports on this have been cited in the car magazines for years . . . as have the absence of refuting studies.

Your product is probably only actually killing a few dozen police officers a year, so this danger has probably been blown out of proportion. That's a reasonable price to pay for the income radar guns bring to towns. It's a good trade-off. As we find out what the less-than-lethal doses are doing to people, we can re-evaluate the product in terms of its benefits to society . . . Wayne

N. B. Sadorian N6WGX, Montebello CA It was a great surprise for me to see my request for information on Motorola's amplified speaker model number 2005B printed in your "Ham Help" column (February 1993).

You will be pleased to know that I am one of those who reads your magazine cover to cover. You should also know that there must be plenty of others out there who apparently do the same. Within the last two weeks I have received not one but two responses with the correct information from fellow ham readers. Although I know I would have done the same, I somehow thought that no one else would pay any attention to the "small problem" I had with a little speaker unit. It really made my day and got me thinking that the world is not that bad yet, as long as there are decent people like you and the rest of us hams who would walk the extra mile to help another human being.

Thanks again for helping your readers, and keep up the excellent work you do with your magazine. ☐

RF Effects Docket Issued

The FCC has released a Notice of Proposed Rule Making to update guidelines and methods used for evaluating the environmental effects of radio frequency radiation. The commission is using the 1992 RF exposure standards adopted by the American National Standards Institute and the Institute of Electronic and Electrical Engineers.

In 1985 the FCC adopted 1982 ANSI guidelines, which resulted in some transmitting facilities being required to prepare an Environmental Assessment if they would expose humans to RF levels greater than those recommended by the guidelines. Under the 1985 guidelines, many low power, intermittent, or normally inaccessible RF facilities were not affected by these FCC rules, including amateur radio stations.

The 1992 ANSI guidelines are more restrictive of RF radiation, and they also extend the frequency range under consideration from 3 kHz to 300 GHz. The new guidelines also specify two sets of exposure recommendations: one for "controlled environments" (usually involving workers), and one for "uncontrolled environments" (usually involving the general public).

Hand-held devices are treated for the first time in the new ANSI guidelines. The 1982 guidelines excluded devices that did not exceed a "specific absorption rate" (SAR) or whose input was 7 watts or less. The 1992 guidelines also contain low power exclusions, but they are more stringent and could require manufacturers to demonstrate compliance with SAR requirements.

The comment date in this docket, ET 93-62, is August 13, 1993. The reply comment date is September 13, 1993. *TNX Westlink Report, Number 648, April 29, 1993.*

HF Digital Mode R.M. Released

The FCC has issued a Public Notice on the ARRL proposal for digital rules for the amateur high frequency bands. The proceeding, which bears the file number RM-8218, originated with submission of the request by the League on February 1, 1993. Copies of the 36-page paper may be obtained from the Regulatory Information Branch at ARRL headquarters. Enclosing a large self-addressed envelope bearing six units of first class postage will speed the reply. *TNX ARRL, Westlink Report, Number 648, April 29, 1993.*

Midland is Back

Midland has returned to the amateur marketplace! The company generally credited with bringing the 1-1/4 meter band to life in the mid-1970s with its relatively inexpensive model 13-509 transceiver now has its own 2 meter hand-held and a full line of mobile antennas. The 73-005 is a relatively inexpensive, yet full-feature, 2 meter talkie that weighs only 6.5 ounces, receives 128 to 174 MHz, and has up to 5 watts output using an optional battery pack (2 watts with the standard pack), 0.16 μ V sensitivity and 200 milliwatts of receiver audio, all packed into a 5-1/2" x 2-1/8" x 1-5/16" case and priced at

\$288. For mobile operation, Midland now has a full line of magnetic-mount, NMO mount and glass-mount 2 meter and dual-band antennas ranging in price between \$28 and \$40. For more information on this new radio and the antennas, visit a factory-authorized Midland dealer.

Form 610 Change

The FCC says that hams no longer need to enter their transmitter location when filling out a Form 610 Amateur License Application Form. This information has heretofore been required on line 8. This would also seem to imply that section 2H (Change in Station Location) is no longer necessary. This change in filing requirements appears to be a cost-cutting move to reduce the labor involved in data entry for amateur radio Part 97 licenses. *TNX W6NLG, Westlink Report, Number 646, March 31, 1993.*

Novice/Tech 30 Meter Petition Denied

The FCC has denied a petition to grant Novice and Morse-code-certified Technician Class licensees access to the amateur 30 meter band. The petition, by William G. Welsh W6DDB, asked that such licensees be allowed CW operation from 10.1 to 10.15 MHz. Welsh argued that the 40, 15 and 10 meter bands currently occupied by Novices and Technicians are becoming less useful due to changing sunspot conditions and interference from shortwave broadcast stations. He also said that the longer antennas needed for operation on 80 meters limited the appeal of that band for Novices and Technicians.

The FCC said that in opening the 30 meter band to the Amateur Service in 1985 it had not included Novices and Technicians in order to promote an acceptable balance between licensing incentives and operating privileges. It followed the same guideline in the opening of the 17 meter band in 1989, the FCC said.

Thus, this petition for rule making was repetitive, the FCC said. *TNX ARRL; FCC; Westlink Report, Number 649, May 13, 1993.*

Sale of Airwaves Gains Support

A Clinton Administration plan to sell much of the electromagnetic spectrum to the highest bidder as a way of increasing government revenues has gained conditional support from industry and regulatory officials. While some government regulators did caution that any bidding process must provide the smaller business with the ability to compete for this resource, they were generally in agreement that such a sale could help offset the rising federal debt.

Congress is currently considering legislation that would transfer some 200 MHz of government-used spectra to the private sector for the development of emerging technologies like advanced cordless telephones, radio LANs, worldwide paging systems, personal locators and other such devices. The House has already passed its version, while the Senate still has its measure under consideration. Both

versions contain wording that would permit the allocation of some of the frequency bands by auction.

While industry leaders see the transfer of this spectra as a boon to the United States economy, several groups, including the National Association of Broadcasters and the American Radio Relay League, feel that the services they represent should be excluded from any competitive bidding of reallocated spectra because of the services they provide. The ARRL is working toward inclusion of language in the final bill to either protect amateur radio from any reallocation or to provide alternative spectra if any reallocation of ham bands shared with the government takes place. The NAB feels that the television broadcast bands should be excluded because the FCC is aware that applications for these frequencies must be based only on their fitness to serve their local communities. *TNX Westlink Report, Number 646, March 31, 1993.*

Jury Finds 60 Hz EMF Not Cancer Cause

In a case that has caused considerable interest among radio amateurs nationwide, a jury ruled on April 30th that high voltage power lines which transversed the home of a couple with a nine-month-old daughter did not cause the child's rare kidney tumors.

The debate over the danger of high intensity 60 Hz electromagnetic fields has been going on for well over two decades, with several carcinoma experts suggesting that prolonged exposure to these elevated EMF fields could be the source or trigger for several different medical problems, especially in children and pregnant women.

Fear of these fields has caused warnings to go out for women carrying children to avoid working near high current machinery or even using electric blankets during their earliest months of pregnancy.

Although more than 100 studies have been conducted in the past 20 years on EMF effects on human tissue, no conclusive evidence for a direct link between the high power fields and cancer has been proven, though several of the studies suggest an elevated incidence of certain tumors.

The jury took only four hours to reach its verdict, and although this is believed to be the first case of its kind involving an action against a public power utility, legal observers believe that it won't be the last. *TNX W6RCL; Associated Press; Westlink Report, Number 649, May 13, 1993.*

Type "N" RF Connectors

How to install and use them.

by Steve Katz WB2WIK/6

In my article in the May 1993 issue of 73 ("The Hows and Whys of Coaxial Cable," pp. 10-19), I hinted that future articles would supply information on the proper assembly and use of RF connectors. The June issue contains an article on the proper assembly of "UHF" type PL-259 RF connectors for use on the popular coaxial cables. Because the UHF connector assembly is rather complex, its discussion consumed an entire article. Now we can address the installation and application of the *best* RF fitting commonly available for amateur use: the Type N.

Type N connectors are available in a wide variety of designs, all of which should be suitable for use through at least 3,000 MHz (3 GHz), and some which are good right on up through 18 GHz! They are far superior to UHF type PL-259 fittings in many respects, although you probably won't notice any improvement in performance unless you use them at or above 440 MHz (70cm). But even at lower frequencies type N connectors are popular and are often found on commercial and military equipment and antennas intended for use on frequencies as low as 1 MHz. This is because type N fittings cost little more than UHF types and meet military standards for moisture and fungus resistance, which UHF connectors do not.

Assembly

It makes good sense to learn how to assemble N connectors, especially the standard male type N UG-21. Don't be scared off by

stories you've heard about these rascals being difficult to install—nothing could be further from the truth.

It is true that military grade type N connectors, (at least the solder type, as opposed to the crimp variety), contain more pieces than UHF's. The number of pieces used vary with connector design and manufacturer, but let's concentrate on the most popular type N for amateur use, the UG-21D/U, which has six pieces: (Photo A) the body, the center pin, the braid clamp, the rubber gasket, the rear washer, and the nut. This sounds more complicated than it is, since the *only* piece that requires soldering is the center pin, which solders very fast and easily. Other than this one piece, connector assembly is purely mechanical and requires only two open-end wrenches, a 5/8" for the rear nut and an 11/16" for the connector body.

In addition to the two wrenches you'll also need a few other standard tools for cable preparation: a sharp single-edged razor blade or X-Acto knife; a pair of small, sharp scissors, such as manicure scissors (I use the set contained in my Swiss Army knife, and this works well); and a light-duty soldering gun (75 to 100 watts is fine) with an appropriate tip. Some 60/40 or 63/37 alloy (tin/lead) radio solder with a rosin flux core will also be used. All these things are required for PL-259 UHF connector installation as well, but for a PL-259 you need a *much* larger soldering gun (like 260 watts) because you need to solder the coax braid to the connector body,

which is *not* required with a type N.

Assuming you are using RG8/U-sized cable (RG8/U; RG8A/U; RG213/U, etc., all of which are 0.405" nominal outside diameter), prepare the cable end as follows:

1. Slide the type N rear nut onto the cable before proceeding with any other operation. The nut threads should face the end of the cable where the new connector will be installed, and the 5/8" (across the "flats") wrench part should face away from the connector, toward the balance of the cable. Slide this down the cable at least several inches to get it out of the way of your work.

2. Next, slide the flat washer (5/8" o.d., and about 7/16" i.d.) onto the cable, over the jacket, so that it will be located between the rear nut and the connector body. The washer has no "polarity."

3. Now, slide the rubber gasket onto the cable, also over the jacket, so that the *grooved* side of the gasket faces the cable end, and the flat, smooth side is towards the washer you just installed in step 2.

4. How long did this all take? Probably about five seconds. Push the three parts already on the cable far enough out of the way so they won't interfere with the rest of your work—you won't be needing them until the very last step when you tighten the connector together.

5. Now you are ready to strip the cable (Photo B). Use the razor blade or X-Acto knife to cut into the cable, applying enough pressure to cut through the outer jacket, braid

Photo A. Here are the six pieces that make up a standard UG21D/U type N connector (left to right): the body, the center pin (note the gold plating), the braid clamp, the rubber gasket, the washer, and the nut.

Photo B. The end of a piece of RG213U, all stripped and ready for pin and connector installation. (Not shown are the rear nut, flat washer and rubber gasket installed in steps 1, 2, and 3.) Note that the center conductor strands are tightly twisted and no braid "hairs" extend beyond the dielectric.

Photo C. Here, the center pin has been neatly soldered on so that solder completely fills the solder hole in the pin. The braid is pulled back over the dull edge of the braid clamp and the gasket, washer and nut are ready to assemble into the connector body.

and dielectric insulation material all at once. Stop when you "hit" the center conductor. Make this cut exactly 5/16" back from the cable end. It is easy to tell, with a bit of practice, how much pressure to apply to cut cleanly through all the layers *without* nicking or damaging the center conductor. The outer jacket will produce almost no resistance to cutting; the braid will produce considerable resistance, but a few "saws" with the knife and you'll be through it. Then the dielectric will produce some moderate resistance, but not a lot. When you cut through these layers and reach the center conductor, it is obviously much harder than the dielectric, and as soon as you feel its resistance, *stop*. If you find that you've nicked the copper center conductor even a little bit, cut off the damaged end of the cable and try again. It won't take long before you're an expert at this.

Once you've cut through to the center conductor (but stopped short of nicking it), hold the blade against the cable with the same steady pressure and rotate the cable 360 degrees to cut all the way around it. When you're done, you should be able to give a gentle pull on the end of the cable to completely remove the stripped section and reveal 5/16" of nice, shiny, undamaged center conductor. With practice, this operation takes about 15 seconds.

6. (For steps 6 through 10, please refer to Photo C.) Now, use the razor blade or X-Ac-to knife to make a cut in the cable's outer jacket *only*, 3/16" down from the end you cut off in step 5. The outer jacket will cut easily—don't apply enough pressure to cut into the braid. If you damage the braid you'll have to start all over, so be careful. Apply very gentle pressure and rotate the cable 360 degrees until you've made a shallow cut all the way around. When you feel the slightest resistance from the copper braid *stop*—you've cut far enough. Pull off the 3/16" of jacket material, exposing this much undamaged braid.

7. Push the open end of the type N center pin onto the cable's center conductor. If you're using stranded-conductor cable (and I

hope you are—it's much more flexible and easier to work with in the long run), be sure that no strands are separated from the bundle before attempting to push the center pin over it. If any strands are separated, gently twist them back together, making sure to twist *in the same direction* as the conductors were originally stranded by the manufacturer. The center pin should "bottom out" on the tip of the center conductor, with the open end of the center pin laying flat against the cable's dielectric. If this is *not* the case, and the pin "bottoms out" with more center conductor still showing between the pin and the dielectric, you need to cut a bit more off the center conductor length. Look to see how much center conductor shows between the end of the pin and the dielectric; pull the pin back off, and cut off that amount of center conductor. Now, push the pin back on. It should bottom out on the center conductor and rest against the dielectric with no extra center conductor showing. Again, this step could take a bit of practice, but after you've installed a few connectors it will take only a few seconds.

8. Lay the end of the cable, with the pin installed, on a flat working surface and place a gentle weight (like a heavy book) on the cable about 4'-6" back from the end of the cable. Twist the center pin until the soldering hole shows on *top*, so you can get at it easily. Apply heat from your soldering iron or gun to the pin, near the hole, and wait a few seconds for the heat to transfer. Applying a *small* amount of solder between the pin and the tip of the iron will make this heat transfer go much faster.

When the pin has reached soldering heat (this shouldn't take more than five or six seconds), apply solder directly to the hole in the pin. After it flows, continue to push a bit of solder into the hole to be sure it "wets" to the cable's center conductor. Don't use too much solder or it will be difficult to get the excess off the outside of the pin (and this will be necessary to complete connector installation and use). Take the iron and solder away, and wait about 10 seconds for the pin to cool off.

Blowing gently on the pin will accelerate this process. When the pin has cooled down so that it's not too hot to touch, pull on it gently to be sure it is well attached to the center conductor. If it pulls off, the solder didn't "take," indicating either not enough soldering heat, not enough solder, or an oxidized center conductor. If the center conductor looks bright and shiny, it's not oxidized. If it has a dull or oxidized appearance, there's something wrong with this piece of cable and it probably shouldn't be used anyway. Try again, and with practice you'll find the pin and conductor will "wet" very well and the pin will be impossible to pull off with your hands.

9. Assuming the pin is properly soldered, inspect the outside of the pin to see if excess solder has flowed onto it. Excess is any amount that causes a "bump" in the diameter

Photo D. The completed, installed type N connector. When the rear nut was tightened a very small space remained between the nut and the connector body. This is perfectly normal. Using high-quality, open-end wrenches for final assembly avoids scratching or nicking the connector plating and leaves a shiny, weatherproof surface.

of the pin. A thousandth of an inch of solder is not a problem, but ten thousandths probably is. If excess solder is on the pin, use a very fine grit emery cloth or very fine nail file (not a large machinist's file or rasp!) to gently file it away. You don't want to file away at the center pin's original plating, which is likely to be a very fine layer of gold. Again, with practice there won't be any excess solder anyway.

10. Slide the braid clamp over the end of the cable, with the smaller-diameter end towards the connector pin already installed, and the larger-diameter end, which should be beveled and have a rather sharp edge, towards the bulk of the cable, rubber gasket, washer and rear nut already installed in steps 1 through 3. Gently fold the braid back over the metal braid clamp until all of it is folded neatly against the 3/16" shaft of the clamp. If you trimmed the jacket correctly in step 6, the braid will *end* before the beveled part of the braid clamp. If you cut off too much jacket, braid "hairs" will extend over the beveled portion of the clamp, and this is no good. Some hams just "trim away" any extra braid at this point, but this defeats the purpose of using a type N connector: If the braid is too long, that means too much jacket has been removed, which also means too much dielectric will now be exposed between the clamp and the pin. This will ruin the geometry of the installation, make "seating" the connector

difficult, and defeat the purpose of using such excellent "constant impedance" connectors. If you made a mistake, it's better to chalk it up to experience and start over with step 5.

11. You are now done with all the critical operations. All that is left is to screw the connector together. Push the connector body over the pin and onto the cable, with the threads "first," towards the bulk of the cable. If no excess solder is present on the pin this should happen quite easily. You might meet with just a little resistance as the pin inserts itself into the Teflon dielectric of the connector body, but a bit of a "push," and it will be on. This will place the braid clamp fully inside the connector body as well, as you will see. When you've pushed the body onto the cable, and all steps have been done properly, the tip of the center pin should be about "flush" with the end of the connector, and the rear end of the braid clamp will be fully inserted inside the body, now recessed about 3/16". If this *doesn't* happen, you didn't follow some instruction. Think it out, and try again.

12. Slide the rubber gasket down to the connector end of the cable until it seats itself on the rear (beveled, sharp) end of the braid clamp. These two pieces are designed to "mate," and the beveled end of the braid clamp will end up inside the rubber gasket. If you're thinking that the braid clamp will cut

the rubber gasket in half when the connector is fully tightened on, you're correct: This is part of the design.

13. Now, slide the flat washer down to the rubber gasket so that it rests against the flat side of the gasket and is fully inside the connector body.

14. Slide the rear nut down to the connector body until it mates with the body's threads, and gently twist the nut clockwise to screw it into the connector body. After four or five twists you should begin to feel some resistance to further threading. Now is the time to get out those two open-end wrenches! Use the 5/8" wrench on the rear nut, and a *thin* 11/16" wrench on the "flats" of the connector body (a "fat" or "thick" wrench usually won't fit—there is only about 3/16" space here for the end of the wrench). Hold the body firmly while threading the nut into it until you meet considerable resistance to further threading. At this point, the rear nut should either be "bottomed out" right against the connector body, or close to it, with a *very small* space showing between the nut and the body. You're done! (See Photo D)

Although this took a lot of description, complete installation of the UG21D/U type N male connector takes only about two to three minutes for the beginner, and far less time for an experienced technician. When I worked in an engineering lab many years ago I'd take an entire day about once or twice a year just

The ears have it!

“The R8 is like a breath of fresh air, with its ground-up engineering and up-to-date digital control from the front panel. I am very pleased to see a quality HF receiver of American manufacture that should successfully compete on the world market.”

*Bill Clarke
73 Amateur Radio Today*

When we introduced the American-made R8 Worldband Communications Receiver, we knew it would be judged by some very discerning ears, experts accustomed to the finest in short-wave listening equipment from around the world. After listening to the world on the Drake R8 loud and clear, they have delivered a decisive verdict.

They appreciated the R8's sensitivity, clarity, simplicity, and all-around versatility so much that many of them declared the R8 simply the best of its class. High praise, indeed, from very well-traveled ears.

But why take the word of mere

experts? Put the Drake R8 to the test yourself with a 15-day money-back trial period on factory direct purchases, and let your ears be the judge. If you're not impressed by Drake's quality, performance and ease of operation, all in a receiver costing less than \$1,000.00, return the R8

Receiver within 15 days, and we'll refund your money in full, less our original shipping charge. To order your R8 factory direct, for more information, or for the dealer nearest you, call **1-800-723-4639** today. We're confident that once you've listened to the R8, your ears will hear of nothing else.

R.L. Drake Company

U.S.A.

In touch with the world.

CIRCLE 147 ON READER SERVICE CARD

to build type N "patch" cables for the lab, and could usually assemble 50 or 75 such cables per day, with two connectors per cable. This is a lot of connectors, considering I'd take lots of breaks to avoid total boredom.

To test your completed connector assembly and installation, hold the connector firmly in one hand, grab the cable about six inches away in the other hand, and give the cable a firm pull. You should *not* be able to pull the connector off the cable. In fact, even 50 pounds of tension will not pull off a properly installed type N because the braid clamp has amazing strength. You might also want to use an ohmmeter to check for the possibility of a short circuit between the pin and body of the connector, but if you've followed directions, this is *extremely* unlikely.

Caveats

If you use *foam* dielectric cable (any brand) or Belden 9913 type cable, do *not* expect the standard UG21D/U center pin to fit the center conductor! Foam cables and 9913 both use "oversized" center conductors (due to the lower dielectric constant of the insulation material used) which is larger in diameter than standard RG8A/U or RG213/U military types, and will not fit the standard pin dimension. Thankfully, special type N connectors *are* available for these non-standard cables. They are often sold as UG21-9913 or some such nomenclature to indicate they are

supplied with an oversized pin specifically to accommodate the special cables.

If you use double-shielded cable like RG9/U or RG214/U, the braid may *not* fit in a standard UG21/U braid clamp/body assembly. These specialty cables also have special connectors made just to suit them. (Frankly, unless you are using the cables to interconnect repeater duplexer cavities, I can't imagine why you'd want to use double-shielded cable. It is not any better in any respect than single-shielded cable, with the sole exception of its reduced RF leakage property. Single-shielded cable like RG213/U has low enough leakage for 99.9% of amateur applications.)

There are varieties of type N connectors which are more complex and contain more pieces than the UG21D/U type described here. For the most part, they aren't any better, except possibly at the high end of the SHF spectrum (above 6 GHz) and therefore might best be avoided. Conversely, there are some excellent type N "crimp on" connectors which require no soldering at all and are thus even easier to install than the one described here. The problem is, some of these cost far more and require specialized and expensive tools for their installation. A good, standard type N UG21D/U connector that will install exactly as described here and is of high enough quality for the vast majority of amateur applications is the Amphenol "RFX" series, part number 82-202-RFX. This six piece

connector, as I've described, is bright nickel-plated for excellent resistance to weathering, and is relatively inexpensive, averaging around twice the price of a cheap UHF type PL-259.

One more note: Yes, type N connectors are available for practically every type of coaxial cable, from subminiature RG174/U to "water-hose" sized RG17A/U. The connectors intended for use with smaller cables (RG174/U, RG58/U, RG59/U, RG8X, etc.) have a smaller rear nut, washer, gasket and braid clamp and a smaller hole in the center pin, but otherwise install as described. The connectors intended for use with larger cables (RG17/U, RG217/U, RG18/U, etc.) have a larger body and rear nut, washer, gasket and braid clamp, and a larger hole in the center pin, but still install as described. If you practice with a piece of military standard RG213/U you'll learn enough to know how to install *any* of the type N varieties on any cable type.

Once you get the hang of it, installing a type N fitting is as easy as falling off a log and much less painful. The type N has lower loss than a UHF type PL-259, especially in the upper VHF and UHF spectrum (300 MHz and above), is more weather-resistant, handles more RF voltage, and will fit more high-end commercial and military equipment and antennas. If you *don't* get familiar with using them, you're missing the boat.

OSO Tutor[®]

Study Aid for the Amateur Radio Exams

New - No-Code Tech. Package!!

Mac[®] IBM[®] Consider the rest, then buy the best!

- Runs on IBM compatibles or Macintoshes
- Programs are available for Novice, Technician, No-Code Technician, General, Advanced and Extra Amateur class exams as well as Commercial Radiotelephone and Commercial Radar Endorsement. Each program sold separately.
- Work with the entire question pools, or study questions automatically selected by the program from your weakest areas.
- Questions current
- Includes full screen graphics, explanations on appropriate questions and, on the IBM version, a pop-up calculator.
- Logs multiple study sessions and allows resuming at a later time. Returns to review missed questions if desired.
- Creates randomly generated sample tests on-line or printed with graphics on Epson/IBM or Macintosh printers.
- Public Domain Morse code tutor is included on request at no extra charge.

Compare the features - No other theory tutor contains the entire question pool, explanations, graphics, progress analysis and automatic concentrated study where you need it.

"Great Programs - I passed the advanced and extra licenses both in one morning! After 12 years as a general. The sample test portion really got me going! See you in the pileups!" **WB9YJF**

"As far as I am concerned, there is nothing like the QSO Tutor program. I have used another and believe me, there is no comparison." **KA3ZBE**

"The most advanced program I've used - Graphics are extraordinary - This program should be your first consideration." **Gordon West - Worldradio**

"Do I recommend the QSO Tutor? Heavily, yes! It really motivated me and it's a great way to test my progress. The learning is a natural by-product of the fun I am having." **Jim Ball - 73 Magazine Review**

Also Available:

QSO Computerizer[®]
The ultimate companion for controlling late model Kenwood rigs.
• Full mouse driven graphical user interface.
• Controls all functions of TS-950, 940, 850, 811, 711, 450, 440 and 140.
• Includes integrated logging, custom scanning, extended memories with annotation, real time S & multi-meters on screen, GMT, in/out-of band conditions by license class, and much more.

Mobile CW Operation

Ham radio's oldest mode keeps rolling.

by Steve Katz WB2WIK/M6

Wait a minute, what's that again? Who would want to operate mobile CW?

I do, for one, and I'm finding a growing number of mobile CW enthusiasts on the HF bands who must agree with me that it's great fun and more productive than mobile phone (SSB) operating. CW is our oldest mode of amateur radio communications, and enjoys an 80-plus-year history of hundreds of thousands of operators and many millions of successful contacts made. Yes, it's old-fashioned, but CW is hard to beat for making contacts with minimal equipment and antennas. Because of its narrow bandwidth and smallest-possible consumed spectrum, CW is an efficient mode of communications. The "newer" digital modes, like RTTY, AMTOR and packet are a bit faster and more automated, but all require specialized equipment that cannot always be managed for field, portable or mobile operations.

Mobile operations, besides being fun and a great way to pass the time while stuck in traffic, lends itself beautifully to CW work. How does one drive a vehicle and send CW at the same time? Easily! How do you drive and talk into a microphone at the same time? It's almost the same thing, and while most

mobile phone operators have had at least one experience where the mike cord got entangled in the steering wheel or knocked over a cup of coffee sitting on the dashboard, a properly laid-out mobile CW station will never encounter these difficulties! How does one concentrate on driving and copy CW at the same time? Easily! Of course, you must copy "in your head," and not be reliant on pencil and paper, lest your mobile CW operations become deadly hazardous.

Based on my several years' experience in operating mobile CW, I have developed a few ground rules by which newcomers to the art must reasonably try to abide:

1. It helps to be a good CW operator to start with. Sloppy sending or poor copying ability will make mobile CW work nearly impossible. Practice at home for as long as it takes to become proficient in CW work, and wait until you start receiving unsolicited compliments on your "fist" before attempting mobile CW work.

2. It helps to have small, uncomplicated equipment. While a new TS-450S might make a good mobile rig, it has too many knobs and buttons, which might be a distraction. I'd stick with simple, inexpensive, sol-

id-state (and no-tune) rigs. My latest acquisition for mobile CW work is the new MFJ model MFJ-9020, a 20 meter (only) CW (only) transceiver which occupies less space than the average 2 meter FM rig, weighs almost nothing, mounts anywhere, and has a list price of only \$179 (I got mine for \$169, brand-new). See Photo A. This little rig works incredibly well and has only four front-panel controls, one of which is the ON/OFF switch! Who needs S-meters, output level meters, dual VFO's, memories and so forth while they're driving 60 mph on the freeway? Surely not I.

3. Permanently mount your keyer paddle in the most convenient and comfortable place possible. I have mine, an MFJ 442B-X (electronic keyer and Benchner paddle in one small box), attached to my center console between the two front seats of my car, between the gearshift handle and the parking brake handle—a nearly perfect spot, at a reasonable height to make sending very comfortable. See Photo B. Route all wires and cables so they're not in the way at all, and are preferably hidden from view altogether. (I have mine "tucked away" under various parts of the console cover materials.)

Photo A. The little MFJ QRP-CW rig will mount just about anywhere, and is so light that a plastic dash will hold it just fine. I used an old bracket from a Radio Shack CB rig (or something), modified slightly for the MFJ rig.

Photo B. The MFJ/Benchner keyer/paddle combination works well and is mounted with Velcro™ to the center console between the front seats of my car. Convenient, handy, unobtrusive and just the right height for easy keying while mobile!

4. Use an external speaker for the receiver, preferably one that can face directly at you. I use an amplified speaker to help overcome road noise: a great deal from Radio Shack, model 21-541. This speaker, which requires a source of 12 VDC power as well as audio drive, produces 8 watts of undistorted audio, sounds great, and costs about \$25.

5. Since mobile stations must use compromise antennas due to space limitations, use the best mobile antenna you can find (whether it be purchased or home-brewed). I use a Hustler™ fold-over mast with screw-on resonator/whip assemblies, mounted on a heavy-duty "ball" (3/8"-24 thread) on the rear fender of my station wagon, with the ball height 32" above the road surface. The antenna, with the 20 meter resonator/whip installed, is 86" long and 62" of its length is completely above the roof line of the vehicle. It works so well that I often can't believe it! I've worked about 45 states and 70 countries with this system so far (in the past few months). There are many mobile HF antennas on the market, and most of them will work well if properly installed.

6. If you like DX, stick with the higher HF bands (20 through 10 meters). Conditions are better and the antennas are more efficient, and cover greater bandwidth, than ones for 30-40-80 meters. (Although 30 meters, being a digital-mode-only band with enforced power restrictions, might be kind of fun from the car—I haven't tried it yet.) Twenty meters is probably "open" more hours per day, and more days per year, than any other band, but 17 and 15 meters aren't too far behind, and 12-10 meters can be great daytime bands in the winter months. Over the last two winters (1990 and 1991), using a Radio Shack HTX-100 10 meter 25W rig and an 8' long "CB" whip (cost: \$9.95), I worked mobile CW DXCC.

7. If you *really* like DX, try a mobile power amplifier! I use a home-brewed one (shown in the photograph) which cost about \$60 to build and uses a pair of MRF247's to develop 100W output power with less than 5W drive across the HF spectrum, 3-30 MHz. This amp was a cinch to build and is essentially identical to the Communications Concepts, Inc. (Beavercreek, Ohio) model EB-63, which sells for \$89.95 in kit form, without cabinet or heat sink. My little amp sits tucked away in the corner of the trunk, just a few inches from the antenna base. (See Photo C.)

8. Answer CQs on an active band; only call CQ when the band's nearly dead. No matter what you run, your mobile signal will not compete very well with base-stations using higher power and efficient antennas. (However, I have been able to work weak DX stations right through enormous pile-ups when I've been parked at advantageous locations. Using 100W and my mobile whip, while parked on a good mountaintop with a clear horizon in all directions, has done better for me sometimes than my legal-limit station at home. Driving or parking along an

Photo C. The trunk compartment with the hatch door removed. The 12 VDC cooling fan is mounted to the hatch cover and blows directly on the mobile amp's heat sink, which is normally just a few inches below the fan when the hatch is closed. The amp can be seen to the right.

ocean beach isn't bad, either.)

9. Be sure to make your own vehicle as free of ignition noise in the RF spectrum as possible. You can't control other vehicles on the road, but almost any motor vehicle can be improved in this area. Simply using resistor-type spark plugs and shielded ignition wiring, regularly replaced when worn, goes a long way towards minimizing ignition noise. My Volvo wagon, factory-equipped, happens to be a very low-noise vehicle, but many aren't.

10. Lastly, when using long or top-heavy mobile antennas (as many are) it often pays to "guy" them a bit to prevent damage from high-speed driving. My Hustler 20 meter whip would place too much strain on any conventional ball mount when traveling at high speeds (let's not discuss *how* high) if it weren't secured with a piece of string to the roof rack of my car.

So much for suggestions. How are mobile CW contacts made? No sweat! Same as home-station CW contacts. You either answer someone else's CQ, call CQ yourself, or break into a CW QSO if it sounds interesting. Your mobile rig will *have* to have some sort of break-in capability (full QSK or "semi-QSK," which is usually the same as VOX on SSB) so you only need to touch the paddle to send. After just a bit of practice you'll be having long CW rag-chews with the best of us. Operating mobile phone or CW is all the same—if you can't chew gum and walk at the same time, mobile operation on any mode is not for you. But if you've had no problem with VHF-FM mobile work, then CW HF mobile work is not any more difficult, provided you're a proficient CW operator to begin with.

Personally, I *like* CW. It's very relaxing to me, and easier to listen to for long periods than phone. Probably the great narrow-band-

width CW filters that allow only one signal to pass to the speaker have a lot to do with this. You can't use a 500 Hz filter on SSB, but on CW it's the norm. Even my little MFJ-9020 has a factory-standard narrow CW filter (with an even narrower one available as an option) which, for the most part, is narrow enough to allow receipt of just one signal at a time, even during crowded conditions. While headphones make CW operation even easier at home, I'd not recommend them for mobile work: They're illegal to use while driving in most states, and might restrict your ability to hear emergency sirens or horns honking. As with any mobile work, the task of controlling your vehicle must take priority over a QSO. Occasionally you might need to forget about your QSO and make an emergency maneuver—just do it, and forget about the QSO. Your contact will probably still be there after the emergency is over, but if not, so what? There will always be another contact.

I guess in addition to being a proficient CW operator, it pays to be a good driver! I'd not recommend mobile CW work (or maybe mobile work of any kind) for brand-new drivers who are still learning the ropes, or for nervous drivers who consider the task of keeping their car on the road an enormous job that requires 100% concentration and then some. But for those of us who drive comfortably in all kinds of conditions, and those who, like me, log 50,000 miles per year on the roads with zero accidents, mobile CW operation should be as easy as falling off a log. And speaking of logs, don't forget to keep one in your glove compartment to record all the great DX you're going to work!

Hope to hear you on the CW bands. For now, this is WB2WIK/M6 (mobile, 6th call area) QRZ DX?

Telephone for brochures: (800) 432-8873
Price Class: \$269

Does your radio miss you when you're not home?

Did you work late and miss your sched, again? Did you miss that rare DX contact that waited for you to get to work before transmitting? Do you want to let your friends try out your rig without the hassle of throwing a party? Well, now there's a solution for these problems and more: HamLink—the interface between your telephone and ham radio. It allows remote operation of your HF, VHF, or UHF transceiver. Any time you're near a Touch-Tone phone you can control your radio almost as if you were home.

The TWF Super System, a 15-repeater (440 and 1.2) membership group, recently installed a HamLink. We are certainly enjoying giving it a workout! Our members were already comfortable with the idea, because they regularly use our three remote base repeaters by operating HF radios remotely using the DTMF tones on their 440 transceivers. But now, with HamLink installed, they're able to work HF even from work or from friends' and relatives' homes. For the first time, remote CW! With a speaker phone, it's easy to share the fun.

Club members and elmers can make HF stations available to other hams this way. We found the unit's voice announcement of frequency and mode worked great for sight-impaired members.

The HamLink can be interfaced with receivers and transceivers which are computer controllable (although no computer is required). The interface cable between HamLink and the radio is specific to the radio's manufacturer and can either be purchased or home-brewed from the wiring diagrams and parts lists in the manual. We installed our unit on a Kenwood TS-940S.

Installation was simple and the instructions were clear and easy to follow. The four cables that make up the interface are for the computer port and external speaker (all compatible radios) and the jacks for the CW key and microphone (transceivers only). The other connections are for power (either AC or 12 VDC) and, after initialization, the telephone line. Initialization consists of introducing your radio to HamLink, entering the security code, and setting the telephone answer mode.

The telephone can be answered after a spe-

Photo A. The AEA HamLink Model HL-60.

cific number of rings or, if HamLink shares the phone line with an answering machine or fax, it can be set to answer immediately after a hang-up and call-back. The telephone answer mode can be changed remotely as well.

We can call HamLink with any Touch-Tone phone. After entering the security code, there we are—listening to the band according to the frequency and mode we were last on. We can easily change to whatever frequency our radio is capable of receiving.

This means that, depending on the radio, you could listen to any frequency: the AM broadcast band, WWV, shortwave broadcast band, 2 meter FM, 20 meter upper sideband, etc. The radio can be tuned to a specific frequency or pulsed up or down in 10 Hz, 100 Hz, 1 kHz, or 5 kHz increments. With a little practice you will easily be able to tune in all the modes, including sideband signals.

When you have tuned in a station and you are ready to transmit, depress the "★" Touch-Tone button; then on you will be transmitting. When you are done transmitting, depress the "★" button again to put the radio back into receive.

You may also select either of the two VFOs or the radio's memory mode. Then you can select different memories or scan the memories. You can request the frequency the radio is on at any time and the interface will reply with a "human voice" telling you the exact information. You may also inquire about the mode, such as USB, LSB, AM, narrow FM, wide FM, CW, and RTTY, (although HamLink is not recommended

for RTTY use.)

You can even send CW through the HamLink via a Touch-Tone button on your phone. You may not achieve great speed, but it might just be good enough to grab that rare country that you have been seeking that only comes around while you are at work.

The AEA HamLink is very small (8" x 5" x 2") and only weighs three pounds. The unit is not polarity sensitive, so if you accidentally hook the power up incorrectly you will not smell smoke! The unit draws only 200 mA. So, with a 12 volt DC powered transceiver, it could be used for emergency communication in an earthquake or flood.

You can also plug a cordless phone base into the RJ11 jack inside HamLink, then just carry your cordless handset around your home to operate your transceiver.

A sightless and otherwise handicapped operator may find it especially advantageous to use a cordless phone as a control unit.

Hardware Requirements

In some cases you may need an additional computer interface board. These accessories can be ordered from the manufacturer. As of this date, the following radios and computer interfaces will work with the ARE-60:

- All ICOMs that have a CI-V computer port.
- The ICOM 751A has a CI-IV port and requires a UX-14 adapter to convert it to the required CI-V buss.
- Yaesu FT-890, FT-990, FT-1000, FT-747GX, and FT-757GX2. The Yaesu do not require an

additional computer interface.

Any Kenwood radio with an active computer port will work, but some radios need interfaces: The Kenwood TS-440 and R-5000 require an IC-10; the TS-711 and TS-811 require an IF-10A; the TS-940S requires an IF-10B; the TS-140 and TS-680 require an IF-10C; the TS-690, TS-450, TS-850 and TS-950 don't require an interface; the TS-50 requires an IF-10D.

Please note: More radios are being added to this list.

These computer interface boards are usually installed inside the radio. Not all dealers have the boards in stock so it is a good idea to get them on order at the same time that you order HamLink.

One of the best things about the ARE-60 is the ease of installation and setup. It took exactly 17 minutes from the time I opened the box to my first on-the-air contact.

I highly recommend that you order the optional cable kit for the radio you are going to use. It's inexpensive and very well-made. You merely plug in the cables from HamLink to the radio and from a Touch-Tone telephone to a RJ-11 connector inside HamLink.

You program HamLink with any standard Touch-Tone phone, inputting the type of radio you are using, as described in the very-well-thought-out operating manual. Then unplug the phone and connect a phone line to the RJ-11 phone jack on the rear of HamLink. You're ready to start having fun. That's all there is to it!

Our club gave HamLink a thorough workout. We set up a unit at our Orange County Super Station, where we have a full-size three-element 80 meter beam, six-element KLM tribander and a full-size 40 meter beam. To test for RFI we used an Alpha 87A running the legal limit. At a special club meeting we gave out copies of instructions for HamLink, along with the security code and phone number. For the next couple of weeks there were many phone

calls by members trying out the system and making contacts. The Touch-Tone codes are very straight-forward and there was very little problem in getting the members of the club up to speed.

They were able to use some of HamLink's auxiliary functions to switch antennas when needed. They found absolutely no RFI and everyone commented on the superb audio on both receive and transmit. In fact, the stations that were contacted via HamLink most of the time had no idea that we were operating remote via telephone.

All comments from members who tried HamLink were positive and most of them wanted to install a full-time dedicated station using it.

One of the neat things about HamLink is that you can listen to any frequency that the

transceiver is capable of. Many of the club members are also shortwave listeners and particularly liked tuning in a shortwave broadcast station, then using the 5KHZ step feature to step their way up and down through the short-wave broadcast band.

The only negative thing I could find with HamLink is that if you are not careful you could accidentally transmit out-of-band. You have to check the frequency announcement often as you are tuning around to make sure that you did not hit an out-of-band frequency by mistake.

HamLink does everything as advertised, and at \$269 it's a great bargain.

Contact David R. Corsiglia at 858 Lenz Drive, Anaheim CA 92805; telephone: (704) 535-5528; Fax: (714) 520-9087.

Frank felt that a 25 minute dissertation on canning okra was appropriate repeater traffic during the rush hour snow storm.

X-BAND TRANSMITTER

Miniature (2 1/4 x 3 3/4 x 1") GaAs microstrip transmitter provides 10 dBm centered at 10.525 GHz. Integrated microstrip patch antenna eliminates the need for an external antenna. Advanced matching techniques secured good temperature stability with low frequency pulling. Great for long-range testing of radar detectors, calibration of radar receiving equipment, and point-to-point communication links.

Most Revolutionary High-Frequency Amateur Radio Antennas in 20 years!

The FLYTECRAFT™ SFX Line of Monoband Vertical HF Antennas

- 5 unique models for 40, 30, 20, 15, 10 meters. Each only 9 ft. tall (10 meter is slightly shorter).
- Precision internal wound helix gives full-size, incredible performance - world-wide DX or domestic.
- Praise from everywhere: ENGLAND - "Your vertical sounds great!" CZECH - "I can't believe your antenna is only 3 meters high!"
- Instant set-up and tear down, or leave up permanently - unobtrusive; ideal for antenna-restricted areas. Separates down to 4 ft.
- Antennas boast low angle radiation.
- Easiest-To-Use antenna made! Uses 2 shortened radials with RADIALCOILS™ - stretch them out or coil them up. (10M uses 3.)

The Hewlett Packard HP 34401A Digital Multimeter

Hewlett Packard Direct
Instrument Sales
5301 Stevens Creek Blvd.
Building 51LSC
Santa Clara CA 95052
Telephone: 1-800-452-4844
Price Class: \$995

Add a top quality test instrument to your workbench.

I know several hams who will spend thousands of dollars on the newest rig this year but who don't own a useful digital multimeter. I don't have money to drop on new gear, but I do require a digital multimeter I can count on. I spend much more time at the workbench than at the operating table.

After going through a pile of off-brand digital multimeters, I decided that I needed something better than what the local Radio Shack carried. So, last year at the Dayton Hamvention, I started to look for a new bench-style digital multimeter.

My wife and I happened to stop in front of the Hewlett Packard booth. I took a quick look, told my wife that "HP" means "high price," and started walking away. Then an HP salesperson walked up to us and started talking.

What he showed me changed my mind about HP. The HP 34401A is a 6-1/2 digit, high performance digital multimeter in a bench-top style case. The HP 34401A does so many things that calling it a mere digital multimeter doesn't do it justice.

Features Abound

The HP 34401A has a highly visible vacuum-fluorescent display. It also has built-in math operations such as Min-Max, Null Value, High Limit, Low Limit, dB REL, etc., as well as continuity and diode test functions. The "hold" feature lets you make hands-free readings. How about an auto trigger set to take a specific reading at a certain time interval? The HP 34401A will even tell you how many times it's been calibrated!

You can set the resolution from 4-1/2 to 6-1/2 digits. You can turn off the autorange feature and use manual control. Two- or four-wire resistance checks make reading low resistance values easy. You can measure frequency up to 300 kHz as well.

Other features of the HP 34401A include an HP-IP (IEEE-488) interface and an RS-232 interface, both standard. You can program the HP 34401A with standard programming languages such as SCPI, HP 3478A and Fluke 8840. You may also use the HP 34401A in a remote interface setup. You can even set it up as a "go/no go" tester.

A front panel switch selects either the front test probes or the rear probes (a set of test probes comes with it). There are so many features that it's hard to keep track of them all.

Putting the HP 34401A to Use

Hewlett Packard includes two manuals with the HP 34401A. One is the user's guide and the other is a service manual. The manuals are super! They're easy to read, and you can find what you're looking for without digging through layers and layers of material.

Each HP 34401A comes from the factory with its own specifications and a certificate of calibration sheet. You know the amount of error on *each* range on almost every function. The DMM goes through about 100 separate tests before passing final calibration. You can have the HP 34401A calibrated to MIL-STD-45662A specs if you desire for an extra charge. You may also send the HP 34401A back to Hewlett Packard at any time to be re-calibrated for about \$90.

Photo A. The Hewlett Packard HP 34401A digital multimeter.

Each time you turn on the meter it does a quick self-test. You can do a more extensive test by holding down the "SHIFT" button when turning on the power. The HP 34401A will respond with a "PASS" on the digital readout.

Of course, the most common things we do with a digital multimeter is to measure voltage, current, and resistance. The HP 34401A excels in these areas. The HP 34401A measures voltage in the following ranges: 100mV, 1V, 10V, 100V, 1,000V (750 VAC). Maximum resolution is 10 nV on the 100 mV range. AC voltage is true RMS and AC-coupled. The HP 34401A will measure current from 10 mA to 3 amps.

Resistance ranges from 100 ohms to 100 megohms. Maximum resolution is 100 micro ohms on the 100 ohm range. The HP 34401A utilized either a two- or four-wire resistance measurement system. For normal resistance checks, the two-wire system works just like any other digital multimeter. But for low, low resistance checks, you'll get the best results with the four-wire method. By using the second set of test leads, you reduce the amount of resistance between the digital multimeter and the resistor you're trying to measure.

The HP 34401A uses a menu system to access sub-menus from the front panel. This is discussed in a very straightforward manner in the user's guide. There are plenty of diagrams to help you navigate the menus in the

user's guide. All you have to do is follow the prompts on the display to access the menu system. It's much easier to do than to explain, but the HP user's guide does an excellent job.

Operation is straightforward and very simple. Just select the function you desire and you're off and running. The autoranging is as fast as any I've seen. You don't have to wait for this meter to keep up with you.

There are several relays inside that you can hear switching on and off as the HP 34401A selects the proper range. After awhile I got used to the clicking and found that I could use the relays as an audio feedback when the meter would switch ranges. Let's say you're looking at the output of a voltage divider and it should be 7 volts. If you're busy flipping the switch on the rig you're testing, it's hard to keep an eye on the HP 34401A display. But, if you hear the HP 34401A flip a relay, you know your test point went over 10 volts. That's where the relays switch over.

I'm hell on digital multimeters. I always forget to switch from resistance before going to volts or current to frequency. The HP 34401A is very forgiving. I've only had to replace the current fuse twice and both times it's been because of operator error.

The Bottom Line

I love it! When the service manual says

the mixer should have 0.1785 volts on the emitter, the HP 34401A will let me know. No more guessing, no more wondering if the test meter is accurate, no more hassle with service personnel telling me my test meter is wrong.

I had some trouble with the local power company with low line voltage. I told the service person I had low line voltage. I was then asked how I knew the voltage was low. Was I using a department store meter? No! I'm using an HP 34401A by Hewlett Packard. Two hours later a repair truck arrived and found the problem.

Is there anything I don't like about the HP 34401A? Well, there is one little item—the marketing. Hewlett Packard says that the HP 34401A is their "low end" instrument. I don't like spending \$1,000 and then being told that I got a "low end" product. Their new "within budget, without compromise" is better.

I would have liked to have had a higher current rating: up to 10 amps instead of only 3 amps. You can add an external high current shunt for taking high current readings if you want.

Yes, it does cost a thousand dollars. But think about that for a second. Would you want to have someone fix your \$2,600 rig with a \$24 meter? This is a case where you really get what you pay for.

EASY-KEY CW KEYER KIT

- WORKS GREAT ON ANY RIG
- PERFECT CW IN ONE NIGHT
- IDEAL FOR CODE PRACTICE, TOO!

Add to your CW fun with our low cost CMOS Keyer Kit. You'll send clean code that's a pleasure to copy, self completing dots and dashes with properly weighted spacing and timing are all programmed into the CW-7's design. Assembly of the keyer is fast, easy and fun, our step-by-step instructions lead you to a finished unit in only one evening. For beginners, the CW-7 makes an ideal code practice oscillator — learn the sound of perfectly formed CW right from the start and have a nice piece of ham gear, too! Built-in sidetone, adjustable pitch, front panel speed and volume controls and convenient 9 volt operation are featured. The CW-7 is the ideal companion to our QRP transmitters or any other rig you may own. Manual also includes details on constructing economical CW paddles. To give your project a finished, "store-bought", professional look, use our custom case and knob set that also matches our QRP receivers and transmitters.

CW-7 ...CMOS KEYER KIT\$24.95
CWC ...MATCHING CASE SET\$12.95

DELUX CODE KEY

Adjustable, heavy duty brass base with ball bearing pivots. Designed for hard usage. 3/16" plated contacts.

\$11.75

CODE PRACTICE

OSCILLATOR & MONITOR
3" SPEAKER, HEADPHONE
TERMINAL, VOLUME & TONE
CONTROLS USES 1 9V BATTERY.

LEARN COMPUTER THEORY BY BUILDING THIS KIT DIGITAL TRAINER MODEL MM-8000

Starting from scratch you build a complete computer system. Our Micro-Master trainer teaches you to write into RAMs, ROMs and run a 8085 microprocessor. You will write the initial instructions to tell the 8085 processor to get started and store these instructions in permanent memory in a 2816 EPROM. Teaches you all about input and output ports, computer timers. Build your own keyboard and learn how to scan keyboard and display. No previous computer knowledge required. Simple easy to understand instruction teaches you to write in machine language. Upon completion of this course you will be proficient in computer technology.

- Uses the 8085 Microprocessor
- Uses the 2816 EPROM, electrically erasable programmable ROM
- Uses the 8156C, 2048 Bit static MOS RAM with I/O ports and timer
- Memory expandable option
- Built in 5V power supply
- 28 key keyboard
- Complete with lesson manual, instructions and experiments

\$119.95

REGULATED POWER SUPPLIES 13.8 VDC

Perfect for ham equipment, CB's, car stereos and other 13.8 VDC items. LED on indicator, short circuit protection. Binded post output. 2 year warranty.

A Tilt-Over/Swivel Antenna Mount for Recreation Vehicles

Take your full-size vertical on the road.

by Gene Beaver W4PVI

In the summer of 1982, Dot (MYL) and I decided that we were going to take a year's tour of the country in our 22' Mini-Motorhome. I most certainly was going to operate the HF bands, but I didn't want to be confined to a mobile antenna all that year.

Installation of an antenna on the roof was impractical due to the height involved because the antenna would not clear low hanging trees, bridges, etc. A quick-connect

would mean climbing the ladder each time it was used. Not very convenient!

I had a Hustler 5BTV Vertical on hand. To solve my problem I only had to figure out how to haul this tall antenna and how to make it quick and easy to put up and take down each time it was used.

I had been a member of the RV Service Net for a couple of years, and knew Chuck W8UCG (SK) (the originator of the Uni-Strut antenna mount on Airstream trailers). I decided to adapt the mount to my motor home.

Construction

After taking some measurements, I realized that if the Uni-Strut was used and the antenna base was to be about 12 inches above the roof, I would have to do an awful lot of climbing up and down the motor home's ladder in order to complete the installation and then do the required tuning. That didn't appeal to me at all. I had to find

a way to swivel the mount as well as fold it over.

The answer came out of the plumber's shop, where I obtained the following materials:

- 1 length of 1" galvanized water pipe
- 1 length of 1/2" water pipe
- 2 1/2" end caps
- 1 1/2" female coupler
- 1 1" female tee joint
- 1 1" floor flange
- 1 1" el (female one end, male the other)

I cut the 1" pipe into three lengths—one 97", one 18", and one 9"—and threaded on all ends. (The 97" length was required for installation on my present Allegro motor home and most likely will have to be changed for your rig.)

The floor flange was fitted to one end of the 97" length and the el to the other. Then I attached the center of the tee joint to the el. I tightened the last two joints snugly, then

Continued on page 31

Photo B. Close-up of the tie-down rope attachment.

Photo C. Working on the antenna is easy—just swivel and tilt.

Tilt-Over Swivel Antenna

Continued from page 28

backed off half a turn. These are the points that allow the antenna to be raised and lowered and to be swiveled from side to side.

Next, I fastened the 18" length to the top of the tee and the 9" length to the other end.

The 63" length of 1/2" pipe (threaded at both ends) was passed up through the 18" length pipe, the tee joint and the 9" pipe. An end cap was installed on the top. The 1/2" coupler and a 3" length of 1/2" pipe were attached to the bottom.

Then I slid a heavy-duty key ring (yes, like a car key ring) over the bottom end of the 1/2" pipe, installed the other end cap, and attached a 6-foot length of 3/8" nylon cord to the key ring.

The entire assembly was set up vertically, with the floor flange resting on the rear bumper to which it was attached with counter-sunk screws.

The bumper now supports the weight of the mast and the antenna when attached.

Installation

The 97" pipe is attached to the roof ladder, approximately 60 inches up from the bumper. This provides the lateral stability. If it is not convenient to support the mast at the ladder, a suitable two-point brace can be used at a point on the RV where screws are already in place.

Once the mast is in place, and the antenna is in the "up" position, the 1/2" "handle" should be attached to the ladder or some other support.

You will be able to come up with your own method of securing the handle when the antenna is in the up position. This is necessary to assure that the antenna stays in the vertical position when operating.

Next, I installed the antenna on the 18" pipe. The antenna bracket was installed as high as the U-bolts would allow, to prevent the mounting pipe from interfering with the radiation pattern.

The antenna can now be lowered by holding the handle and the nylon cord. Once the antenna is in the horizontal position, the handle can be slid forward with the cord and fastened to prevent sliding back during travel.

The advantages of the "sliding handle" are obvious when observing the rear overhang of the handle before being slid forward. When lowering the antenna for travel, slide the 1/2" pipe forward and secure with the rope. Reverse the procedure for raising. You will need to install some kind of cradle on the roof for the antenna to ride in while underway.

I installed only the bracket and first antenna section while working on the roof. Once that portion was complete, the mast was folded and swiveled so that the antenna rested on a chair that was on the ground. All remaining work and tuning was done without once having to climb atop the motor home.

The "Grounds" for Lightning and EMP Protection

Second Edition

K PolyPhaser

Hot Off the Press

The "Grounds" for Lightning and EMP Protection

SECOND EDITION

A comprehensive hands-on guide to proper grounding installation, measurement and maintenance for direct lightning strike survival. Over 100 pages with new informative "how-to" charts, graphs and pictorials. From high rise to mountain top, for radio sites and computer LANs, this is a *must* read book.

Only \$22.95 (includes first class postage).

PHASE 3D WILL BRING:

Space to virtually every ham through:

- Higher power transmitters
- Higher gain antennas
- Three axis stabilization

More bands:

- Downlinks on 10 Meters, 2 Meters; 70, 13, 5 and 3 Cm.
- Uplinks on 70, 23 and 5 Cm.

Higher Orbit:

- 48,000 km. (29,000 mile), 16 hour orbit for increased coverage and visibility for many hours each day.

PHASE 3D NEEDS YOUR HELP!

A contribution of just a few dollars from EVERY active amateur will insure that this new marvel gets into orbit.

MAKE YOUR CONTRIBUTION TODAY!

You are also invited to join AMSAT and receive the *AMSAT Journal* so that you too, can follow the progress of Phase 3D and other exciting amateur satellite activities. Dues are just \$30 annually in the U.S. and \$36 in Canada and Mexico - \$45 elsewhere.

Make Sure It's Grounded

While this is not a technical article, there are three things that are very necessary to an efficiently operating mobile antenna of this type: ground, ground and ground.

I use 1/2" copper braid from the antenna base to the "closest possible point" to the roof or ladder in several places, and then down the ladder to the vehicle chassis. I do the same from my radio to the chassis.

Do the very best job you can with grounding during installation and forestall any future problems from that source.

The Safety Factor

Everyone needs to adhere to standard safety practices when working atop anything with ladders, etc. Be especially careful when raising the antenna. I personally know two hams who have raised their antenna into a power line. No harm came to either, but one had a "real hot" trailer for a while. **IT COULD HAVE BEEN FATAL! ALWAYS LOOK UP BEFORE RAISING THE ANTENNA.**

It's easier than you think to drive off and leave the antenna in the air. Most of the time you won't get out of the RV park before disaster strikes. A tree or a power line will get you. I know one friend who stopped at a fast-food joint for lunch, put up the antenna to check into a net, and then drove off. He got five miles down the Interstate before leaving his 75 meter coil on top of the bridge and the rest scattered all over the highway.

I had a sign made with two words: **ANTENNA DOWN?** I attach it to the steering wheel and gear selector as soon as I stop.

Photo D. Pull the 1/2" pipe all the way out with the rope, then pull down to raise the antenna. Tie off the rope to secure.

The two things I wanted most from this tilt-over/swivel mount were versatility and convenience. I got both. I put the clock on myself once when pulling into a rest stop and wanting to check into the RV net. I started the clock when I put the gear selec-

tor in park, went to the rear of the motor home and raised the antenna, got back in the driver's seat, keyed the rig and stopped the clock. Time elapsed: 30 seconds.

The next thing I did was to hang my "ANTENNA DOWN?" sign.

Expanded Range Direct-Reading Inductance Meter

Build this cheap choke checker.

by Arthur C. Erdman W8VWX

The inductance meter I described in the January 1992 issue of *73 Amateur Radio Today* works well but it is limited to about 10 to 250 μH . The basic circuit creates a pulse, the width of which is directly proportional to inductance. A digital voltmeter (DVM) reads the average value of the pulse train. Readers have inquired about how to extend the range to lower and higher values. Much thought and experimentation provided an answer: Place the unknown inductance in series with a known inductance. This avoids having the circuit inductance approach zero at the low end of any scale. Also, the range of linearity is narrowed, making the circuit quite practical.

As a specific example, I used a fixed 10 μH inductance on the "0" to 25 μH range. Now the circuit sees 10 to 35 μH .

The pulses never get vanishingly narrow. Insert a 100 μH for the 0 to 250 μH range and, finally, use a 1,000 μH for the 0 to

2,500 μH range. See Figure 1.

These inductors (5% tolerance) are available for less than \$1 each from Mouser Elec-

Figure 1. Basic measuring scheme.

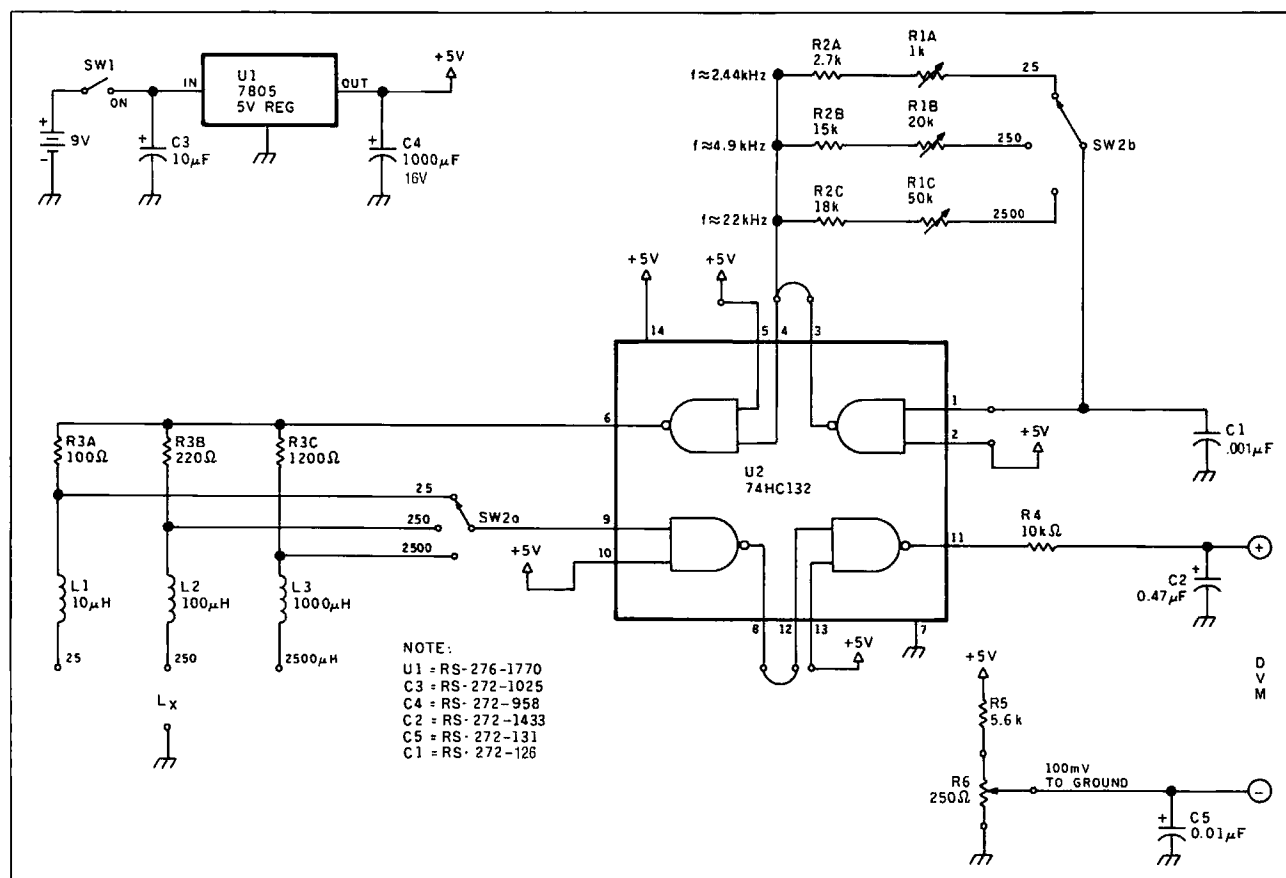

Figure 2. Schematic for the expanded-scale direct-reading linear inductance meter.

Figure 3. PC board pattern and parts placement for the expanded-scale direct-reading linear inductance meter.

tronics. The offset voltage due to this method of measurement is simply counteracted by a bucking voltage.

Linearity is excellent because the greatest change in pulse width on any range is only 3.5 to 1. Without the series inductance, the linearity must be over a much greater range. For example, without the series inductance, the "0" to 250 μH range would never reach "0" because the pulse would be too short to pass through the gates. If 10 to 250 is readable, the linearity must be over a 25 to 1 range.

The following indicates the scale resolution:

- 1) 0 to 25 μH ; 10 mV/1 μH

- 2) 0 to 250 μH ; 1 mV/1 μH

- 3) 0 to 2,500 μH ; 1 mV/10 μH

Circuit limitations prevent the 0 to 2,500 μH range from having greater sensitivity. Figure 2 indicates the complete circuit.

Construction

To avoid switching of the critical inductances, I elected to have a separate jack for each range. I am always trying out different circuits (and values) so I seldom use a printed circuit. The most convenient approach that I've found is to use an "experimenter's plug-in board." Radio Shack carries these. They are listed as "Solderless IC Breadboards." I used their board, catalog number

276-175, approximately 2" x 3-1/2", with 270 connecting points. Number 22 wire fits snugly into the holes. So do 1/4 watt resistor leads, most capacitor leads and best of all, integrated circuit legs.

Drilled and etched PC boards are available for \$4.25 plus \$1.50 S&H from FAR Circuits, 18N640 Field Ct., Dundee IL 60118.

Tune-Up

(The L meter and DVM power supplies *cannot* be both AC line powered or the bucking voltage will be shorted out due to common grounds.)

1. Adjust the bucking voltage to 100 mV. To do this, connect the DVM from the read-out negative terminal to ground (chassis).

2. On each range, short the L_x terminal to ground and adjust the proper pot for 0 volts at the read-out terminals. That's all that is required.

If you discover that inserting a known inductor in the circuit produces a slight error on the read-out, remember that your standard is only within 5%. Coils in the 250 to 2500 μH range have widely varying DC resistance, causing linearity errors. Iron core coils read truer due to less wire resistance than air core coils of equal inductance.

Deluxe Function Generator

This simple project has many uses.

by David Cripe KC3ZQ

A function generator is one piece of equipment found in the lab of nearly every electronics technician and engineer. In conjunction with an oscilloscope, a function generator can be used to test or troubleshoot most gear found in the hamshack. Unfortunately, commercial function generators are priced well out of the range of most hams, and good used ones don't often appear at hamfests. Consequently, I decided to design my own! This simple, low-cost function generator features TTL, square-wave,

triangle, and sine-wave outputs, and portable battery operation.

Design

I started out by defining the features I wanted. This project had to be low-cost, using commonly available parts. It had to be portable, operating from batteries. It needed to have a TTL output for testing logic circuits, as well as variable-amplitude square, triangle, and sine-wave outputs. The sine wave output must be relatively pure, with

the amplitude of the harmonics less than 1% of the fundamental frequency. The frequency range of the function generator had to cover 100 hertz to 10 kilohertz, which would include most of the audio range. After a few hours of breadboarding I arrived at a circuit which met all of these requirements.

See Figure 1. This is a fairly simple design using only three ICs. All of the parts are available at your neighborhood Radio Shack, or from any well-stocked junk box.

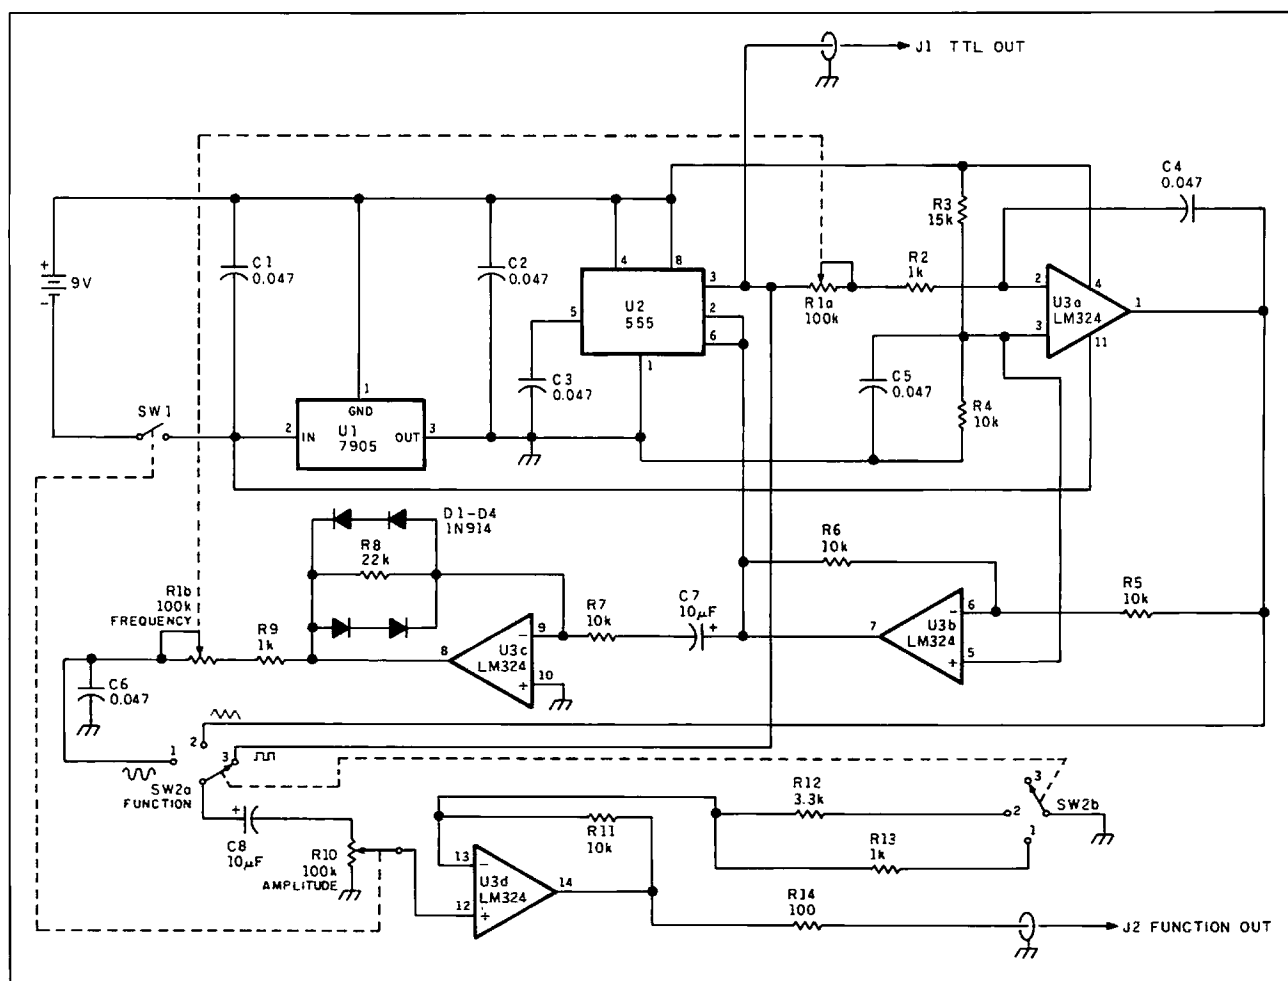

Figure 1. Schematic for the Deluxe Function Generator.

The circuit can be built conveniently on one of Radio Shack's solder-pad breadboards, such as their part #276-168, or you can purchase an etched and drilled PC board from FAR Circuits, 18N640 Field Court, Dundee IL 60118 (\$4.50 plus \$1.50 S&H).

After mounting the circuit in a folded aluminum box, I found its small size and portability made it easier to use than any of the commercial function generators I was familiar with. I actually ended up taking it to work with me to use at my job for those applications where portability is preferred over accuracy. I am now building my second one!

The heart of the function generator is a U2, a 555 timer. These ICs are tremendously useful devices, with high-current outputs, capable of driving TTL loads. It is configured as a somewhat unconventional square-wave oscillator in this circuit. The square-wave output of U2, pin 3 of the 555, is integrated by U3a, one section of an LM324

quad op amp, producing a highly accurate triangle wave. This waveform is then buffered and inverted in U3b, and fed back into pins 2 and 6 of the 555, its trigger and threshold inputs, respectively. This causes U2 to produce its square-wave oscillation. The frequency of oscillation is determined by R1a, one section of a 100k stereo volume control pot.

We now have a circuit which generates a square wave and a triangle wave. Obtaining a sine wave is a bit more difficult. Those of us who had a little math in college may remember some theorems from a fellow named Fourier, telling us that if we take a sine wave and add its third, fifth, seventh, ninth, etc., harmonics at the correct levels, we come up with a triangle wave. Conversely, low-pass filtering the harmonic components from a triangle wave should leave us with a sine wave. It turns out that if we clip the upper and lower 33.3% off of the peaks of a triangle wave the resultant trapezoidal waveform contains no third harmonic energy. Passing this waveform through a simple, one-pole low-pass filter gives us a sine-wave of sufficient purity for our needs. Diodes D1 through D4 perform the function of waveform clipping in U3c. The low-pass filter consists of R9, R1b (the second section of the 100k stereo volume control pot), and C7. Since the cutoff frequency of this filter, controlled by R1b, tracks the oscillator frequency, the sine wave output of has a nearly constant amplitude over its frequency range. This sine-wave is very pure, with no harmonic higher than 1% of the fundamental.

The last section of U3 is used as a buffer amplifier for the function generator output.

Figure 2. PC board pattern and parts placement.

Switch SW2a, one section of a two-pole, three- (or more) position switch, is used to select the square, triangle, or sine wave to be buffered. The gain of the buffer is set by R10, a 100k log taper volume control pot. The circuit on/off switch SW1 may be integrated into R10. Since the amplitude of the square, triangle, and sine waveforms at SW2a are not equal, the second section of SW2 is used to scale the gain of the U3d buffer so that the amplitudes of the three waveforms are roughly equal at the output.

A 7905 voltage regulator, U1, creates a stable 5 volt source for the 555, as well as the split (+5, -4 volt) supply required by the op amp.

Give this project a try. I can think of worse ways to spend a rainy weekend afternoon than building a simple, inexpensive project that has as many uses as this one.

Parts List

C1-C6	0.047 µF	272-134

A Universal Speech Processor

An easy upgrade for your transceiver.

by Bob Roehrig K9EU1

Most of the more expensive HF transceivers today have some form of speech processing. Less expensive rigs have either marginally effective processors or none at all.

Older radios, especially tube-type units such as Drake, Swan, and Collins, do not have any processing at all. Over-modulation protection, if any, is accomplished by means of an ALC circuit. Many hams (believing that ALC is to be used as a form of compression) drive their units well up into the ALC region on the meter. Some rigs that have ALC have no means to monitor its operation. ALC is intended only to protect from over-modulation on occasional peaks. The ALC indicator should just barely show action once in awhile. An ALC circuit is not a substitute for a speech processor.

Unless you have a fancy "high-end" rig with a decent internal processor, it is well worth the time to construct an outboard unit. QRP enthusiasts who operate SSB can get the most out of a low power rig with the use of an effective processor.

Construction

The unit described here is an easily-assembled processor that can be used with any rig available today. Its small size even makes it possible to install the unit inside some rigs, rather than in a separate box.

I chose to build my processor in a mini-box so it could be used on several rigs. (I also plan to add a keyer circuit for CW in the same box.) The circuit was assembled on a small piece of "hobby board" from Radio Shack. A drilled and etched PC board for this project is available for \$4.25 plus \$1.50 S&H from FAR Circuits, 18N640 Field Ct., Dundee IL 60118.

The input circuit of the processor consists of an op amp with a voltage gain of 10 and has an input impedance of 100k. This should accommodate almost any type of microphone in use. The output of this stage is adjusted by R5.

Diodes D1 and D2 rectify the audio signal. The DC voltages are filtered by C3 and C4. These capacitors also determine the time constant of the circuit. The voltage from the rectifiers is applied to diodes D3 and D4 to forward bias them. These diodes act as variable impedance devices. The higher the voltage applied to them, the more they "turn on," shunting more of the audio signal to ground.

Capacitors C5, C6 and C7 isolate the DC levels from the audio portion of the circuit.

The output amplifier performs two functions: It has a gain of 10 to make up for losses in the processor part of the circuit, and also transforms the relatively high impedance of the processor to a lower impedance so the processor cannot be loaded down. R13 is the output level adjustment.

Power decoupling is accomplished by R14 and C9. R1 and R2 form a voltage divider to properly bias the op amp inputs at half the supply voltage. The supply voltage is not critical. Anything between 6 and 24 volts can be used. Stage gain remains constant, regardless of supply voltage. The supply must be well filtered to eliminate hum. With a 12 volt supply, the average current drain is only 2 mA, so the unit can easily be powered from a small 9 volt battery.

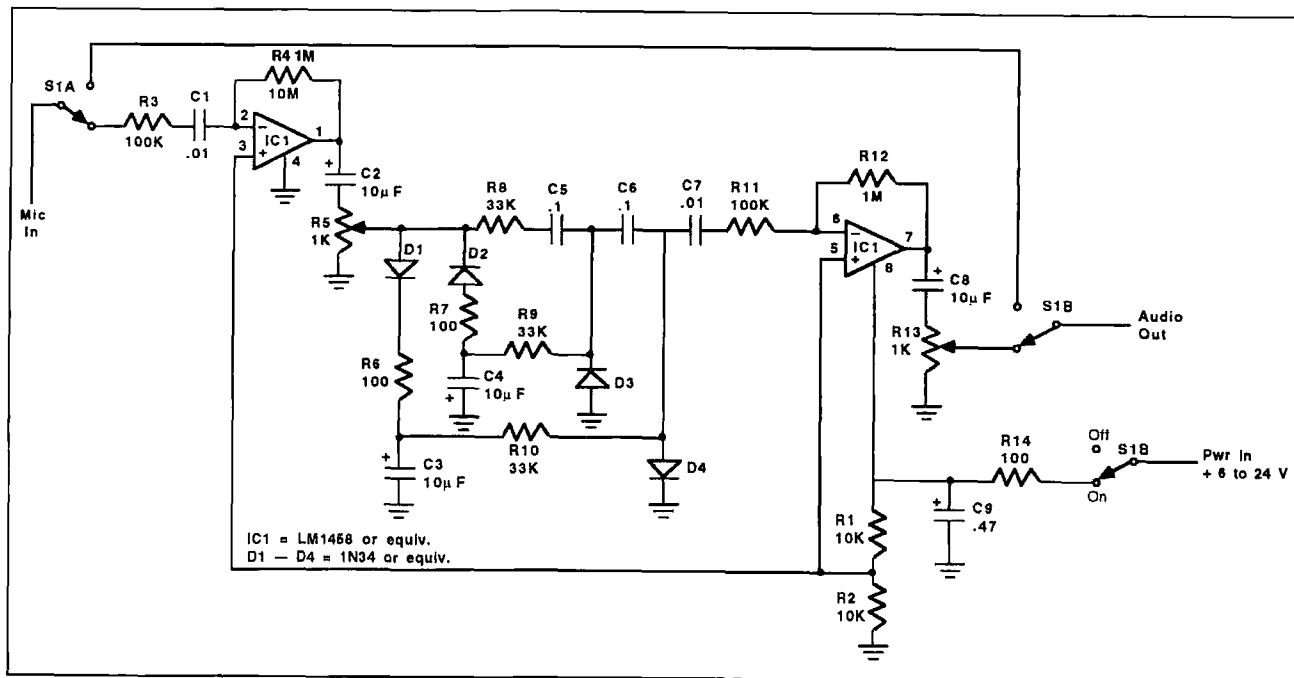

Figure 1. Schematic for the Universal Speech Processor.

Personal Autopatch

Make and receive telephone calls from your mobile or HT with your own personal autopatch. Connect to phone line and transceiver microphone, PTT, and speaker jacks.

NEW! Now with memory backup.

- Full duplex or simplex with courtesy beeps.
- Programmable local and long distance codes.
- Automatic CW identification.
- Microprocessor controlled timeout protection.
- Controlled by VOX or carrier detect.
- Regenerated DTMF or pulse dialing.
- Separate external remote control output.
- 1.5"Hx4.6"Wx5.05"D shielded metal cabinet.

Personal Autopatch SDP-600.....\$249.95

12Volt power adapter.....11.95

BASIC REPEATER INTERFACE

ONLY \$50!

Have your own repeater or link system!

Easy repeater setup without modification to your radio gear, simply plug in and go! Ideal for emergency or portable/mobile repeaters! The BRI-2 works with ANY receiver (or scanner) and ANY transmitter. Super sensitive VOX operation makes setup quick. Includes Hang and timeout timers. Passive audio interface for clean audio. Only 4.5" x 3.5" x 1.5" and choice of 12 VDC or 9V battery power (please specify when ordering). ORDER BRI-2 \$50.

Five to dual in-line pins over the BRI-2-DUAL model which contains two of the above as the box. ORDER BRI-2-DUAL \$45.
The BRI-2-EB has a built-in "remote base" interface so you can link your repeater with other frequencies or repeaters. Simple and easy to use. ORDER BRI-2-EB \$45.

Figure 2. PC board pattern and parts placement for the Universal Speech Processor. A drilled and etched PC board for this project is available for \$4.25 plus \$1.50 S & H from FAR Circuits, 18N640 Field Ct., Dundee IL 60118.

Adjustment is best performed with the aid of a scope but can also be done with a high impedance meter (VTVM or FET input meter or DVM).

Connect the scope to the output (wiper) of R5, or connect the meter across C3. When the word "FOUR" is spoken into the mike at a slightly lower than normal level, adjust R5 so the scope indicates about 200 mV peak-to-peak, or the meter reads about 50 mV. At a normal level the scope should not peak over 2 volts peak-to-peak, or the meter should be less than 1 volt.

Compression starts at about a level where the meter reads 50 mV. At levels above 100 mV the output remains constant. With a sine wave applied to the input, the output remains sinusoidal until the voltage across C3 reaches about 3.5 volts. In other words, with a variation of from 1 to 6 volts peak-to-peak at the output of R5, the output level remains constant and does not clip.

R13, the output control, is adjusted so that with normal speech the mike gain control on the rig is at its normal position.

A word of caution here. While there is a constant output level for an input variation of 30 dB with a signal generator source, this does not mean you can operate your rig so its meter reads maximum output. A signal generator is not the same as speech! Because the attack time of the processor is not instantaneous, there is some overshoot at the beginning of

speech input. Final analysis should be done with the aid of a scope that is monitoring the RF output of the rig. Unless you can determine peak modulation levels in this manner, do not hit peaks as indicated on your rig's meter, greater than half your normal maximum available power.

In addition to increasing the average modulation percentage, this processor also helps intelligibility by tailoring the frequency response. At 300 Hz, the response is down 6 dB. Low frequencies in the voice range waste energy and should be reduced, especially if you have a bassy voice.

Signal Quality

I have found that it is very difficult to get valuable information about the quality of my signal from anyone listening to it. If you tell someone that you are using a processor, chances are they will tell you it sounds bad no matter how well it is working.

A good way to judge the quality of your signal is to operate the rig into a dummy load and pick it up on another receiver. If necessary, attenuate the RF signal into the receiver so it stays below S-9. Record the received signal on a good quality tape recorder and listen to the results. Reduce the RF level into the receiver to S-5 or less and record the results again, with and without the processor, for comparison. If you are pleased with the results, so should everyone else who hears you.

Stacking UHF Antennas

Get gain with less pain.

by Ronald Baker WB4HFN

Venturing into amateur television or "ATV" for the first time presented me with new and exciting challenges. Not only was I operating at unfamiliar frequencies; I also had to deal with the greater bandwidth needed for video transmission. The most important consideration for me was the antenna system.

Towers and large obtrusive antennas are not allowed in my subdivision. Next to a good antenna system, overall height is the most important factor. For my application, height was not a problem since I live on a hilltop several hundred feet above average terrain. My problem was to design a good antenna system that would be physically small and still provide adequate gain.

Design

In talking with other hams operating ATV, the general recommendation was: "The higher the better, using the biggest antenna you can rotate." Antenna-wise, most of the operators were using antennas with gains of 13.5 dB to 18 dB. Researching various antennas, I found that for the required gain the boom length is 10 to 20 feet. That length would be too obtrusive for my neighborhood. To solve this problem, I set out to design and build an antenna system that would give me a minimum of 14 dB gain with an overall boom length of under five feet.

Not knowing a lot about VHF/UHF antenna design, I first looked at various antenna manufacturers and discovered that Cushcraft makes a beam that covers the 430 to 440 MHz band, with 11.5 dB gain, and a boom length of four feet. It seemed to fit my requirements, except for the gain.

I erected a system using this antenna and found that it performed well, but the lack of gain was very noticeable. The antenna match right out of the box was almost perfect. I measured very low standing wave or reflected power with a Bird model 43 wattmeter at 432 MHz. At this point, the on-

ly thing I needed was more gain. One way to quickly get an additional 3 dB would be to stack two antennas together. Since the antennas are vertically polarized, stacking would eliminate the need for a Fiberglass mast. Normally, a metal mast going through a vertically mounted beam tends to distort the radiation pattern and can affect the overall gain, especially at VHF/UHF frequencies.

There are many different types of UHF beams on the market today, but most are not

the 430 to 440 MHz range. This is the SSB portion of the band and is shared with the upper half of the ATV band. This segment of the band is usually where you will find ATV repeater input frequencies, which will present a good match to your ATV transmitter.

Signal loss in the 420 to 430 segment was noticeably greater. This segment is usually reserved for the ATV repeater transmitters, which have the signal advantage over an individual station. Also, receive signal loss can be further minimized by using a good RF preamp, preferably mast-mounted. Most ATV operators will tell you that using a good RF preamp is essential, no matter what type of antenna design you use.

When it came to stacking UHF antennas, I thought it a simple matter to mount two antennas, hook up a phasing harness, and attach the feedline, WELL . . . ALMOST! Mounting the antenna was a simple task. Using a "T" configuration mast I mounted the antennas on each end with 26 inches separation, as specified by the manufacturer. The actual separation between antennas varies with the type of antenna and boom length. Figure 1 shows the overall construction.

The antenna phasing harness presented an interesting challenge. I had two options for a harness: Purchase one or construct my own. Spending \$50 for a ready-made harness consisting of four coax connectors, one "T" connector, and a few

feet of RG-59, was totally out of the question. Not knowing much about phase harness construction, I hit the books for information. I was surprised to find little information available, and what I did find was vague, with no clear-cut answers. I even contacted the antenna manufacturer where I received a few suggestions, but again nothing definite.

With all the discussion and reading, I was able to determine the length of the cable. The cable from the "T" connector to the an-

Photo A. The stacked UHF antennas.

suited for ATV operations. Most commercially available antennas are designed for the FM portion of the band between 440 and 450 MHz. This type of antenna works well at the designed frequencies, but performance in the 420 to 430 MHz region is compromised because the element length is too short for a proper match. Operating ATV, you will quickly learn that every dB of gain or loss affects picture quality. The Cushcraft model 432-11 antenna is still a slight compromise because it's designed to operate in

Figure 1. Final assembly detail.

tenna must be an odd multiple of a quarter wavelength, minus the length equal to the propagational delay of the cable. Propagational delay is a comparison expressed as the percentage of the time it takes for signal to travel through coax to the time it takes to travel the same distance through free space.

The cable length, including connectors, must be the same on both sides of the "T" connector. The feedline to the "T" connector from your equipment can be any length.

For example, let's use the frequency 432 MHz and RG-59 75 ohm cable.

Our formula is: $CL = MQW \times PPD$

CL = the length of the coax cable in inches, including connectors from the "T" connector to the antenna.

MQW = the odd multiple of a quarter wavelength in inches, at the operating frequency.

PPD = the coax propagational delay, which for RG-59 is 85%. In the formula this number is expressed as a decimal number.

First, determine the quarter wavelength of the operating frequency using the formula:

Quarter wavelength in inches = $2808 / \text{frequency in MHz}$

In our example: Quarter wavelength = $2808 / 432$

Quarter wavelength = 6.50 inches

Next, determine the length of coax needed between the "T" connector and the antenna. For my project I needed a minimum of 35 inches of cable to make the connection from the "T" connector to the antenna. I chose to use the seventh multiple, which gave me an

overall length of 45.50 inches. Next, we multiply this number by the coax propagational delay of 85 percent, as shown below.

$CL = MQW \times PPD$

$CL = 45.50 \text{ inches} \times 0.85$

$CL = 38.67 \text{ inches}$

As shown in our formula, the proper coax length for the phasing harness is 38.67 inches from the "T" connector to the antenna. This measurement is tip-to-tip, with connectors as shown in Figure 2.

Tuning

Tuning the antenna system is a simple task. You must use a power meter or SWR bridge designed for UHF, such as the Bird Model 43. The meters designed for HF and even 2 meters are usually not accurate at UHF frequencies.

After the antenna system has been assembled and mounted on the "T" shape boom, tune both antennas individually for minimum reflected power or SWR. In this step the coax from your equipment is connected directly to the antenna. The phasing harness is NOT connected.

After both antennas are properly tuned individually, connect the phasing harness to the antennas as shown in Figure 1. If everything is tuned properly and the harness is cut correctly, the SWR should still be good, but slightly higher than the reading you had with each antenna individually. At this point, all further adjustments to fine-tune the antenna array can be made by adjusting only one antenna. It doesn't make a difference which one you use to make the adjustments—the important thing is to adjust only one antenna. I tried various methods of adjustment and found that this method works the best.

Overall antenna performance in the upper portion of the band was very good, considering the antenna's size. The manufacturer antenna gain specification for this design was 16.8 dB. Even though I feel this may not be a realistic figure, there was a definite improvement over a single antenna of the same type. In comparing this design with the larger ATV antennas, it performed very close to the antennas in the 10 to 14-foot range that give between 14.2 to 14.8 dB gain.

If you need a good antenna system on ATV and have space limitations, this design works well. At UHF frequencies, height above average terrain is extremely important. Even the best antenna system performs poorly if you're looking into trees, hills or nearby structures.

Figure 2. Phasing harness detail.

Nine to 10

What to do when 10 meters is closed.

by Paul M. Danzer N1II

Just a few short months ago many of us were routinely talking to Europe or Asia with our low power 10 meter mobile rigs as we commuted back and forth to work. Then there were more and more days where our favorite DX friends were too weak to copy, and then more and more days when they could not be heard at all.

The culprit, of course, is the 11-year sun-spot cycle. At the peak of the cycle, which occurred a few years ago, 5 to 25 watts on 10 meters was enough to cover much of the world. Now that we are going down towards the low part of the cycle, more and more often nothing can be heard: "The band is dead."

Leave Your Rig in the Car

The temptation is to say OK—if 10 is dead I might as well take the rig out of the car. But 10 is a funny band; closed one day and suddenly open the next. Quiet one minute and full of DX the next, as the sun erupts and quiets down.

Instead of taking the rig out of the car, you could try to find a use for it when 10 is closed. The converter shown in block form in Figure 1 does just that.

10 May Be Closed but Other Bands Are Open

The 10 meter band extends from approximately 28 to 30 MHz. Your 10 meter rig has a very sensitive and selective receiver. Figure 1 shows a converter which can be built in just one evening. It allows the receiver to cover a shortwave band. This way, when 10 is closed you can monitor a shortwave band instead of the "golden oldies" played on your local broadcast station.

The 9 MHz shortwave band is a good choice. Open at all hours in most places to some part of the world, it is a compromise between the higher shortwave bands (13, 15, 17, and 19 MHz), which tend to be closed at night during this part of the sun spot cycle, and the lower shortwave bands (7 and 6 MHz), which are usually closed during the day.

Picking the 9 MHz band has another advantage—you get the 8 MHz ship band (including weather, telephone calls, and

inter-ship messages) which can also make for very interesting listening.

How Does It Work?

Figure 1 shows the flow of signals in the converter. Your 10 meter antenna is connected to an input network (to be discussed later). A single field-effect (FET) transistor, Q2, acts as an oscillator at 20 MHz. A second FET is used as the mixer. Stations in the frequency range of 8 to 10 MHz go through the input network into the mixer, which adds 20 MHz to their frequency. Thus, a station on 9.1 MHz comes out of the mixer at 29.1 MHz ($9.1 + 20 = 29.1$).

The result is that the marine (ship) frequency band in the range of 8.2 to 8.8 MHz is converted to 28.2 to 28.8 MHz, and the shortwave broadcast band of 9.5 to 9.9 MHz is converted to 29.5 to 29.9 MHz. Don't be surprised to hear shortwave broadcasts outside of these limits since not all countries play by the rules!

Two FETs and One Crystal Do It All

Figure 2 shows the schematic for the converter. The oscillator consists of FET Q2 and a 20 MHz crystal (marked XTAL) in a Pierce oscillator. The circuit is simple, uses a minimum number of parts, and works well with very inexpensive crystals.

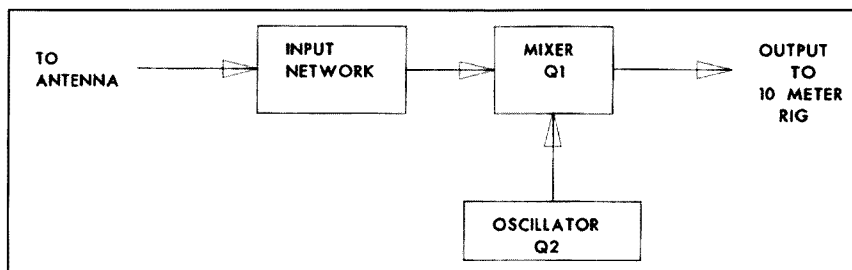

Figure 1. Signal flow.

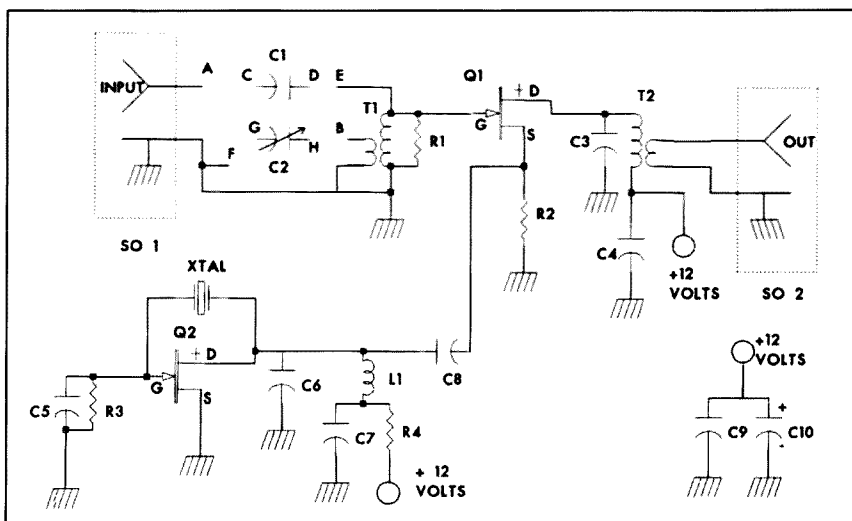

Figure 2. Schematic for the converter.

Q1, also an FET, is a source injection mixer. It produces both the sum and difference of the input signal and the 20 MHz local oscillator. The output circuit, consisting of the larger winding of T2 and capacitor C3, is broadly tuned to the sum frequency range.

We don't really want any selectivity from this circuit since we have plenty of selectivity in the 10 meter receiver connected to it.

The circuit operates from 12 volts. It would probably operate just as well from 9 volts, but since your car supplies 12 volts, that voltage is used. C9 and C10 are bypass capacitors to clean up the 12 volt line a little bit on the converter board.

The Input Network

When your 10 meter rig is connected to your 10 meter antenna and the standing wave ratio (SWR) is low, the antenna looks like a 50 ohm source plugged into a 50 ohm receiver input. However, your 10 meter antenna, when measured at the end of a transmission line, can look like just about anything you can imagine when it is measured at 9 MHz.

That's exactly what we are doing with

this converter—trying to use a 10 meter antenna at 9 MHz. Therefore, as the schematic (Figure 2) shows, the input connector (SO1), two capacitors (C1 and C2), and the input transformer (T1) are important.

These components can be connected in several ways (see Figure 6) to get the maximum signal from the antenna to the converter, and the connection of these parts is part of the simple tune-up process.

Build It in One Evening

The original model of this converter was built on a breadboard unit available from Radio Shack (part #276-174, the Experimenter's Socket). The layout is not critical. The oscillator is built on one end of the breadboard unit, with the converter on the other end. It can also be built on perf board fit with standard "flea" clips if they are available.

But, the best way to construct the unit is with a printed circuit board. Figure 3 shows the layout of the board and the parts placement diagram. The board is available from FAR Circuits, 18N640 Field Court, Dundee IL 60118, for \$3.50 per board plus \$1.50 shipping and handling per order.

T1 and T2 are made from 100 μ H chokes (Radio Shack #273-102). Each choke comes wound with two layers of wire. Only 20 turns of wire are needed for the large winding

Figure 4. Choke winding diagram.

in T1 and T2, so strip off the excess wire until only 20 turns are left, and then reconnect the free end of the wire.

Take the surplus wire you have cut off and wind five turns for the second winding. Twist the leads to the five turns together to keep them from unraveling. Don't be overly concerned about how neat these transformers look—they do not have to be very precise.

Figure 3. PC board and parts placement diagram.

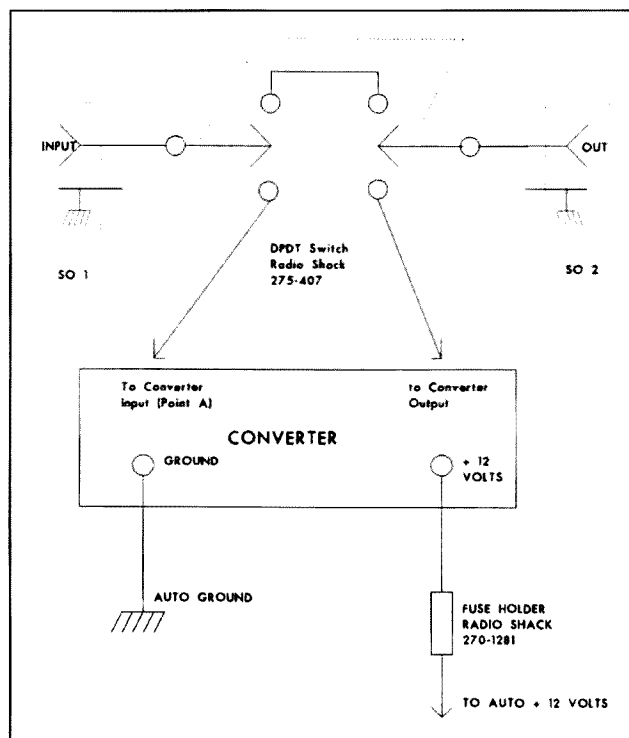

Figure 5. Set up the converter in your car.

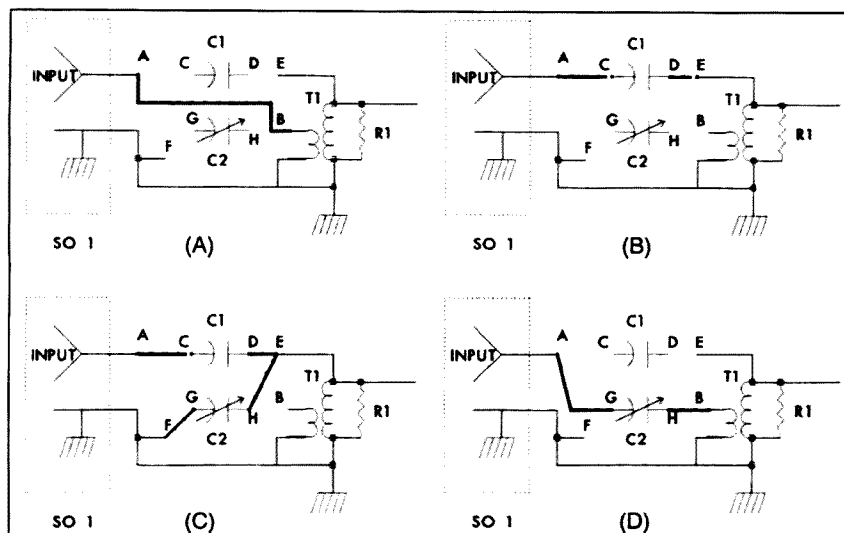

Figure 6. Tune the converter by configuring these jumper wires as shown for best results.

According to the Parts List, C5 is a 4.7 pF. Occasionally you might run into a crystal which does not want to oscillate with this value. In that case wire two identical 4.7 pF capacitors in parallel in place of the single unit.

Plug It In

The converter is connected by removing the antenna lead from your 10 meter rig and connecting the lead to SO1. A new piece of coax with connectors is used to connect the output of the converter at SO2 back to the input connector on the rig. Fi-

nally, the 12 volt input of the converter is connected to a 12 volt source in the car.

It is best to connect the 12 volts through a fuse. The converter draws only a few milliamperes so the fuse will only serve to protect you from a major short circuit. An in-line fuse holder, such as Radio Shack #270-1281 with a 1/4 ampere fuse, will do the job nicely.

If you wish, you can wire the converter with a double-pole double-throw switch, such as that shown in Figure 5. This would allow switching the converter in and out of the antenna line without the bother of removing the antenna line and reconnecting it.

When the converter is connected,

make sure that you do not key your microphone! Transmitting with the converter in the line will probably result in blowing transistor Q1.

Tuning it Up

There is no real tune-up process except for the initial connection of the jumpers in the input network. As I mentioned before, your 10 meter antenna, depending on its size and type, can look like almost any impedance to the converter at 9 MHz. The input network was designed to allow you to try to get maximum signal from the antenna to the converter.

Each of the suggested connections shown in Figure 6 can be tried to achieve best results. The heavy line represents a jumper. Start with jumping A to B as in Figure 6A. Then try some of the other variations to see which provides best results.

Both 6C and 6D include the use of variable capacitor C2. Adjusting C2 can make a major difference or no difference at all, depending on your antenna.

If you mount the converter in a plastic box, don't be surprised if several shortwave broadcast stations come in loud and clear with no antenna at all. In many areas they are so strong that they tend to ride through no matter what you do.

What You Can Hear

The 9 MHz shortwave band is listed as between 9.5 and 9.9 MHz, meaning that you will hear these stations on 29.5 to 29.9 MHz on your 10 meter rig. But don't be surprised to hear them at frequencies as low as 9.1 MHz. The band is pretty crowded and often stations will migrate just to find a clear spot—just as hams do!

When east-west propagation is down on the 9 MHz band, north-south propagation

CIRCLE 20 ON READER SERVICE CARD

usually picks up, so South American stations can predominate at certain times of the day. However, don't be surprised if you hear European stations when you least expect them. Many of them do not transmit from their home countries but use multi-megawatt relay stations in the Caribbean to carry their programs. In fact, the same transmitter, on slightly different frequencies, can be rented to one country's broadcast service for several hours a day and then to another country for a few more hours.

The 8.2 to 8.8 MHz range is a marine traffic band. Several U.S. shore stations provide weather broadcasts on voice at the hour or half hour; the only way to find them for your area is to tune around. Marine stations have two modes of operation: simplex and duplex. On simplex, both the shore station and the ship station use the same frequency. Duplex provides both a ship transmit frequency and a different shore station frequency.

Inter-ship communication (ship to ship) is usually carried on simplex, and telephone calls are carried on duplex. Table 1 provides a number of suggested frequencies to monitor.

The converter also covers the aircraft band of 8.8 to 9.1 MHz. Within this band

you may be able to hear trans-oceanic aircraft providing position reports to air control centers on both U.S. coasts. Listen for a burst of a few audio tones. This is SEL-CAL, or Selective Calling, which means that someone on the ground is dialing or calling a particular aircraft. Table 2 contains the international frequency assignments in this band. There is almost no QRM; you might be surprised at how well some of the aircraft stations propagate when they are transmitting from 35,000 feet.

Variations and Changes

Don't be hesitant to experiment. The converter is not sensitive to changes and has no critical elements. For example, if you use a 13 MHz crystal instead of the 20 MHz unit shown, and take a few turns off the large winding of T1, you can cover the 15 MHz shortwave broadcast band. Changing the crystal to 13 MHz means that your converter output is $13 + 15 = 28$ MHz, so the new crystal provides a different shortwave band.

Try the converter! With just one evening's work you can enjoy your 10-meter rig in the car when the band is closed and you would like to hear something other than a 30-year-old pop tune.

Hierarchical Addressing

This month we'll take a look at a part of packet operation that is both very simple and (apparently, based on mail received here at N1EWO) confusing. It takes just a little understanding of this scheme to make it crystal-clear.

What Is Hierarchical Addressing?

Hierarchical addressing is a scheme which allows packet traffic to be routed easily by the stations that comprise the amateur packet network. It eliminates the need for each station in the chain to know exactly where to send a particular message or bulletin. To understand how it works, let's take a look at the term itself.

Working backwards, we have "addressing." The idea of addressing is easy for all of us to understand. Addressing a packet message is just like addressing a letter. It tells the delivery system—packet network or post office—where to route the addressed item. Then there's "hierarchical," a

word that many people have a tough time pronouncing. Say "hi-ur-ark-ik-ul." What is meant by this word is that the addressing scheme has a hierarchy from very specific—a particular ham—

to very general—a continent. These elements are arranged in a "hierarchy," hence the name.

This is really no different from our previous example of an ordinary letter. Let's compare the two:

To send me mail, you address your envelope:

Jeffrey Sloman
P.O. Box 636
Franklin IN 46131

To send me a packet message, you address it:

N1EWO@N0ARY.#NOCAL.CA.US
A.NA

There are clear parallels between the two schemes. Ignoring for the moment the ZIP code, which actually uses its own hierarchical scheme, let's compare elements directly. The most specific information in each case is the recipient—me, Jeffrey Sloman or N1EWO. This says exactly who should receive the message. It is, therefore, at the very top of the hierar-

formation to the delivery system. However, in order for the system to work, it must already know *something* about what the address means. If it did not, you would have to provide detailed instructions (e.g.: "go three blocks on Main Street and turn left—it's the green house on the right," or a list of every PBBS between you and your recipient) that would be impossible to handle. So the point of the address is to let the delivery system know, in

***"Let me point out something interesting here:
When you address a message you are providing certain
information to the delivery system. However, in order for
the system to work, it must already know something
about what the address means."***

chy. If this were the only information the address provided, a huge file listing the addresses of every possible recipient would have to be kept by the post office—(an impractical situation, since names are not unique)—and by the PBBSs (Packet Bulletin Board Systems) that make up the forwarding network—(not as difficult, but still hard to maintain).

Let me point out something interesting here: When you address a message you are providing certain in-

formation about the desired destination that it can use to get your message there.

The next, less specific, element is P.O. Box 636 or N0ARY. This is the place that the mail will be delivered for me to retrieve (note that a street address serves the same purpose). This is followed by a Franklin and #NOCAL. Notice that there is a "#" in front of "NOCAL." This is because it is an optional, regional destination. The "N"

SCARED OF THE CODE?

IT'S A SNAP WITH THE ELEGANTLY SIMPLE
MORSE TUTOR ADVANCED EDITION FOR
BEGINNERS TO EXPERTS—AND BEYOND

Morse Code teaching software from GGTE is the most popular in the world—and for good reason. You'll learn quickest with the most modern teaching methods—including Farnsworth or standard code, on-screen flashcards, random characters, words and billions of conversations guaranteed to contain every required character every time—in 12 easy lessons.

Sneak through bothersome plateaus in one tenth of a word per minute steps. Or, create your own drills and play them, print them and save them to disk. Import, analyze and convert text to code for additional drills.

Get the software the ARRL sells and uses to create their practice and test tapes. Morse Tutor Advanced Edition is approved for VE exams at all levels. Morse Tutor is great—Morse Tutor Advanced Edition is even better—and it's in user selectable color. Order yours today.

For all MS-DOS computers (including laptops).

CIRCLE 114 ON READER SERVICE CARD

lets the PBBS know how to interpret this element. Many states have regional addresses which help speed forwarding. Your area probably has at least a couple of divisions that you can use to direct traffic. You can ask a local user, write a message to the PBBS sysop (SYSTEM OPERATOR), or just watch traffic go by to find out how your area works.

The next element is IN or CA. These are exactly alike—they name the state to which the traffic will be sent. The packet address has additional information: USA—for United States of America, of course—and NA for North America. This information is assumed by the post office, so it is left off.

Now, while a packet address is written from top to bottom, it is used exactly the other way. By sending a message to the station responsible for the next element, (starting from the least specific), any particular station needs only to know about its own area in detail, (and only generally about other areas). In the example of my packet address, let's pretend we are sending me a message from France. We log on to a local PBBS and compose a message. We address it using the full hierarchical address. The local PBBS sees the very bottom of the address—NA. We are in Europe, so the PBBS knows that this message isn't even on the right continent yet!

The French PBBS need not be concerned with any other address information—it will just squirt the message across the HF link to the North American PBBS which it knows is responsible for handling message bound for North America. Now the North American PBBS, located in Canada, receives the message. It looks at the next element in the address and sees that it is USA. No problem—it sends the message to a PBBS in Boston which it uses to forward US messages. This PBBS—you guessed it—

a message makes is completely dependent upon the network resources available at the time. I just wanted you to get a feel for the utility of hierarchical addresses.

Practical Addressing

So now that you have a feel for what hierarchical addressing is, how do you use it? The fact of the matter is, you are probably better off just using an abbreviated address. That is, you should use just the recipient and PBBS:

"Now you can venture out into the world of packet radio, armed with your new knowledge and ready to send messages to anyone, properly addressed."

looks at the next element, CA. The message gets forwarded to the next PBBS in the chain because it is on the path to California. This process continues until the message arrives at its destination.

Please note that the example above may not reflect reality. Depending upon the availability of links, the French PBBS might have forwarded directly to California. How many hops

N1EWO@N0ARY

This is because the rest of the address is most likely already stored in the PBBSs database, and if you make a mistake, even a small one, in writing out the whole address, your mail will sit until the sysop can straighten it out. If you are confident of your ability to not screw up, you can include the whole address. If you have regular correspondence with a user of a re-

mote PBBS, you need only use the whole address once and the PBBS will remember. If you use a truncated address, and the PBBS cannot fill in the rest, you will probably get mail from the sysop asking for the information.

So, while I can't say you now know everything about hierarchical addressing, you should know enough to feel comfortable with it. Now you can venture out into the world of packet radio, armed with your new knowledge and ready to send messages to anyone, properly addressed.

Survey News

By now, I had hoped to have the survey results compiled for publication. Unfortunately, the whirlwind of activity here at N1EWO has prevented me from doing it. I will, however, have the data available for the next issue. Thanks to all who responded. 73 de N1EWO.

Q An Antenna with No Earth Loss?
A Yes... the answer is GAP's revolutionary technology.

If you're looking for an antenna that can outperform the others and give you the edge, you're looking for a GAP. The Challenger DX-VIII is the revolutionary design that answers your demands for multi-band operation and unequaled efficiency with low noise. This is the technology that eliminates Earth Loss. GAP delivers from an elevated feed; your power doesn't disappear into the ground. Put it up. Turn it on. No tuning. No frustration. GAP delivers everything but the hassles. And — GAP delivers at a fraction of the cost of the "so-called" competition.

Why buy a TNC?
PC HF FAX + PC SWL \$179.00
SPECIAL COMBINATION OFFER

For a limited time, if you order PC HF FAX \$99 (see our other ad in this issue), you can add our new and improved PC SWL 3.0 for \$80.00 instead of our regular low price of \$99.00.

PC SWL contains the hardware, software, instructions and frequency lists needed to allow you to receive a vast variety of digital broadcasts transmitted over shortwave radio. All you need is any IBM PC or compatible computer and an SSB shortwave receiver. The product consists of:

Demodulator
Digital Signal Processing Software
200 Page Tutorial Reference Manual
World Wide Utility Frequency List
Tutorial Audio Cassette with Samples
PC SWL automatically decodes Morse code, RTTY, AMTOR, SITOR, NAVTEX and ASCII.

PC SWL lets you tune in on world press services meteorological broadcasts, ham radio operators, coastal shore stations, aviation telex and much more digital action on the shortwave bands. Why pay for another expensive box when a simple interface and your PC can do the job?

ADVANCED FEATURES:
Tuning Oscilloscope
Digital Waveform Presentations
Auto Calibration and Code Recognition
Continuously Tunable Filter Frequencies
Variable Shift
Adjustable CW Filter Sensitivity
Unattended Capture and Printing
Integrated Text Editor
Integrated Log and Database
Serial to DOS applications
Seamless integration with PC HF Facsimile

Selecting Variable Capacitors, Part I

Variable capacitors are a regular part of amateur radio circuits. While the new generation of hams might see fewer variable capacitors in their modern equipment (phase-locked-loop synthesizers and solid-state RF power amplifiers don't use them like the "old stuff" did), they are still found extensively in antenna tuners, preselectors, and in many—perhaps most—home-brew rigs. Selecting the right variable capacitor requires a little insight into the different types of variable capacitors available. Also, you might be interested in where these "antiquities" can be purchased.

What Are Variable Capacitors?

Capacitors are formed by placing two conductors opposite each other, separated by an insulating dielectric. Different types of dielectrics are used in variable capacitors: vacuum, air,

mica, and poly film are the most common. The capacitance is inversely proportional to the spacing between the metal plates of the capacitor (moving them closer together raises capacitance). In transmitters and antenna tuning units, there must be a trade-off between the wide spacing necessary to increase the working voltage and the narrow spacing required to increase capacitance. The capacitance is directly proportional to the area of the metal plates facing each other (whether by size of the plates or by the number of plates) and the dielectric constant of the insulator between the plates.

Making a capacitor "variable" can be accomplished in several ways: changing the spacing between plates (in compression capacitors), or changing the proportion of total plate area "shading" each other (in most rotary variable and piston capacitors). Compression capacitors are typically used for "trimmer" or "padder" applications. A trimmer capacitor is placed in parallel with the main tuning capacitor

Photo A. Two forms of variable capacitor: straight line frequency (left), and straight line capacitance (right).

itor in an LC resonant tank circuit, while a padder is placed in series with the main tuning capacitor.

Another way to classify capacitors is according to the manner of the capacitance change when the tuning shaft changes. Photo A shows the two different forms: a straight line frequency capacitor on the left; a straight line capacitance form on the right. A straight line capacitance capacitor has a constant capacitance change per degree of shaft rotation

($\Delta C/\text{degree}$). For example, suppose a capacitor is designed to provide a capacitance range of 7.7 to 100 pF, or a range of 92.3 pF over 180 degrees of shaft rotation. That capacitor will show 0.513 pF/deg all across the range. A straight line frequency capacitor uses shaped plates to account for the fact that the resonant frequency of an LC tank circuit changes as the square root of the capacitance changes. These capacitors have a constant frequency change per degree of shaft rotation.

The type of capacitor selected can have a profound effect on the look of a calibrated dial. A straight line capacitance device will cause the frequency units to scrunch up on one end of the dial (you've seen that effect on some AM band radios), while a straight line frequency device will show equal frequency change for every linear dial division. Radio receiver LOs and transmitter VFOs will usually want a straight line frequency type, while certain instruments (such as an impedance bridge) might require a straight line capacitance type.

Two different types of air variable capacitor construction are shown in Photo B. The capacitor in Photo B-1 uses two end plates (one front and one rear), while the capacitor in Photo B-2 uses a single end plate. "Conventional wisdom" suggests that the dual end-plate units offer better mechanical stability so they are better for VFO/LO applications. But in reality, there seems to be a trade-off. After building a lot of VFOs and LOs during the past 30+ years, I can't see the advantage, especially when you consider other sources of drift and shift appear far more severe in those circuits.

Note that the capacitor shown in Photo B-2 uses a ceramic end plate. Others will use a metal end plate, which also serves to ground the capacitor when it is directly mounted to a chassis. The ceramic type end plate makes it easier to "float" the capacitor. There are two ways to do this trick. First, cut a hole in the metal panel wider than the 3/8" threaded

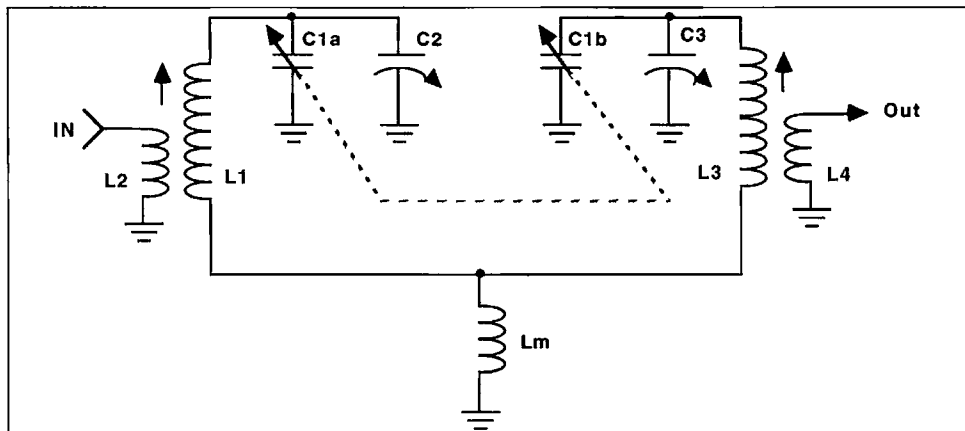

Figure 1. Doubly tuned RF "front-end" selector.

Photo B. 1) Two-end plate variable; 2) single-end plate variable.

Photo C. Two-section variable capacitors: A) both sections the same; B) front section smaller to tune LO (used in superhet radio receivers).

bushing, and a 3/8" hole in an insulator piece of material. The capacitor is mounted to the insulator, and the insulator is mounted to the panel. The second way is to cut the hole larger than 3/8", but also drill two mounting holes on either side of the shaft hole and use the holes in the ceramic end plate to hold small screws.

Photo C shows a pair of dual variable capacitors. The capacitor in

Photo C-1 has two sections that each have the same capacitance range. For "broadcast variables," the normal capacitance range is 10 to 365 pF, although 10-380 pF, 10-300 pF, 9-140 pF, 10-440 pF and 12-500 pF capacitors are available. The 140 pF are typically used in transistor portable radios, and the other values are found in radios from other countries. For most broadcast receiver variables

used in this country, if the two sections are identical, the range is 10-365 pF.

One application of dual capacitors is to tune two ends of a double-tuned RF input LC tank circuit (Figure 1). This circuit consists of two LC resonant tank circuits (L1/C1A/C2 and L3/C1B/C3) that are coupled together through a small mutual inductance Lm. Information on selecting the val-

ue of the mutual inductance can be found in nearly any edition of the ARRL *Radio Amateur's Handbook* (or *Handbook for Radio Amateurs* in later editions). The RF signal is coupled into the circuit through a low impedance link (L2), and out of the tank circuit by another low-Z link (L4).

Getting the two halves of the double-tuned tank circuit to "track" to the same frequency is done by making use of the variable tuning feature of inductors L1 and L3, and the trimmer capacitors (C2 and C3). In most cases, the inductors are adjusted for peak signal output at the low-end of the band, and the trimmers are adjusted at the high end of the band.

Another application of the dual variable is to simultaneously tune both the RF amplifier input and the local oscillator in a superheterodyne radio receiver. The frequencies of these circuits differ by the amount

RANDOM OUTPUT

Continued from page 96

of being a first QSO, this one on the 10 meter Novice phone portion. It was surprisingly similar to my own first QSO. The young newcomer was at a friend's house, "borrowing" the station for his first QSO. He was quite nervous, and admitted to being so. I told him about my first QSO, which helped to break the ice. Boy, first QSOs are sure easier on SSB! I explained to him that he didn't have to give our call signs before and after every transmission, that the goal was to be as conversational as simple communication will allow (advice I give to every new ham I find myself in contact with). We ended up having a nice little QSO, with his friend interjecting comments now and then. I felt I was sort of "paying back" that ham in Dallas, and my high school radio club buddies.

A few days later, I received a QSL card in the mail, thanking me for being a first QSO. I've been a ham for almost 20 years, and I've got a box full of QSL cards. I keep a half dozen or so at my operating position, to remind me of particularly pleasant contacts. I keep the "first QSO" card at the top of the pile. It reminds me of some things it would do us all well to remember now and then.

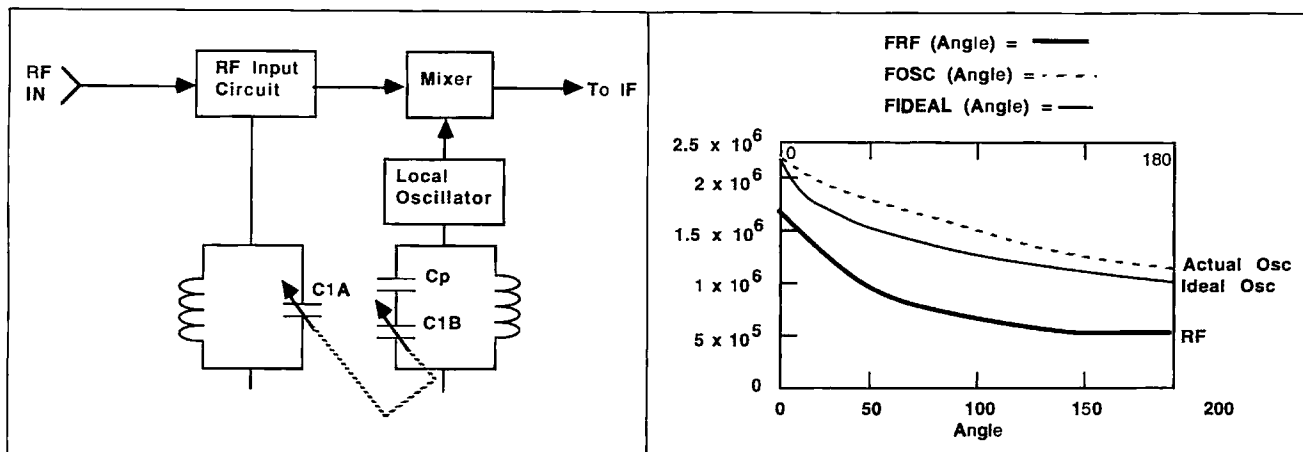

Figure 2. A) Block diagram of superheterodyne front-end showing use of the padder capacitor; B) MathCAD tuning curve for an AM BCB case using a padder capacitor.

of the IF frequency. For example, in a 75/80 meter receiver that uses a 455 kHz IF amplifier, the RF circuit will tune 3,500 to 4,000 kHz, while the local oscillator tunes from 3,955 to 4,455 kHz. The frequency ratio of the RF is 1.143:1, suggesting a required capacitance ratio of 1.143², or 1.306. The LO, on the other hand, has a frequency ratio of 1.126:1, requiring a capacitance ratio of 1.126², or 1.268:1. One method for achieving improved tracking between the RF

and LO is to use a padder capacitor (Cp) in series with the section of the main tuning variable that tunes the LO (C1B in Figure 2A).

There is a little bitty problem with using a padder capacitor to achieve tracking, even though it was once very popular. Figure 2B shows a MathCAD plot of the RF frequency, ideal oscillator frequency, and actual oscillator frequency for an AM BCB case (225 μ H inductor, and 2X 365 pF capacitor). Note the large separ-

ture between the ideal and actual local oscillator frequency curve. This problem is fixed by using a specially designed variable capacitor, like Photo C-2, in which the front section is smaller (and has slightly differently shaped plates in some models). The front section is designed to tune the LO frequency range, while the rear section tunes the RF frequency range. Popular combinations include 8.5-105 pF/15-480 pF and 10-140 pF/12-420 pF.

Next Month . . .

In the final installment of this two-part series we will take a look at transmitting variable capacitors, the differential variable, the split-stator variable and some of the circuits in which these are used. Another topic in Part II will be calculating the trimmer values and inductance values needed for tuning a specified frequency range (like a ham band). We will also look at some sources of supply for variables.

Amateur Radio Via Satellites

Andy MacAllister WA5ZIB
14714 Knightsway Drive
Houston TX 77083

One of the most formidable challenges for the amateur radio satellite chaser is to make a successful voice or packet contact with a space shuttle. Making such a contact will require a level of operating skill, patience and equipment performance not needed for regular hamsat activity.

The amateur radio equipment carried on the shuttle is part of SAREX, the Shuttle Amateur Radio Experiment. Various equipment configurations have been in use since 1983 when Owen Garriott went to space in the *Columbia* on mission STS-9. He operated voice on 2 meters. Many SAREX missions have followed.

STS-56 flew in April 1993, carrying equipment for packet, voice, SSTV and FSTV reception. The mission was a success, with a full schedule of school contacts, FSTV tests, some SSTV activity and general QSOs.

In May, STS-55 carried packet and voice gear, known as configuration "C," in conjunction with the German SAFEX (Shuttle AmateurFunk Experiment) equipment for 70cm FM operation. Comparisons were made between the window-mounted SAREX antenna and the quarter-wave whip attached to the outside of the German spacelab. The whip performed 12 dB better than the window antenna.

Three more SAREX flights are planned this year, including STS-57 in

June, STS-58 in August and STS-60 in November. They will use packet and voice.

The shuttle is typically in a low orbit between 120 and 310 miles, with an inclination between 28 and 57 degrees. This means short passes, a variable orbital decay rate and low elevation angles for antennas. There are also large Doppler shifts of the signal frequencies.

"Such obstacles cause some amateurs to give up while inspiring others to try every means available to make a contact. Before attempting a shuttle contact be sure to observe the rules of the game."

The ham-astronauts cannot operate on every pass for general contacts. The work timeline and scheduled contacts with schools and families take precedence. The packet equipment, if on board, is usually active for those passes when the astronauts plan no other ham activity. But even the packet has been shut down when the antenna window is required for photography and other experiments.

The SAREX antenna is mounted in one of the cabin windows and can be shadowed by the spacecraft. Signals can be difficult to copy for as much as half the pass. This affects uplink signals as well.

SAREX Procedures

Such obstacles cause some amateurs to give up while inspiring others to try every means available to make a contact. Before attempting a shuttle contact be sure to observe the rules of the game.

First, *never* transmit on 145.55 MHz; second, *never* call the shuttle if transmissions from the spacecraft are not on 145.55 MHz. Many stations have been heard calling on 145.55 MHz. Although the SAREX Motorola HT is capable of reception on 145.55 MHz, experience has shown that split-frequency operation is necessary. Voice uplinks for all stations except Europe start at 144.91 MHz and go to

144.99 MHz in 20 kHz increments. Except in emergencies, the SAREX HT will *never* be set to receive on 145.55 MHz.

For packet activity, the uplink is 144.49 MHz and the downlink is 145.55 MHz. When sending connect requests, call W5RRR-1. The specially modified Heathkit TNC uses the call-sign of the Johnson Space Center Amateur Radio Club with a "-1" SSID (sub-station identifier) at the end. The packet operation does not currently use a standard 600 kHz split, so be sure to use a radio capable of the odd split.

During voice activity, if the ham-astronaut appears to be engaged in a

scheduled contact on 145.55 MHz *wait* until the QSO is complete. It's better to get a QSL for a "heard" contact than to interfere with a school or family pass. Special QSL cards that differentiate between SWL and QSO activity are no longer printed.

Making Contact

Using the rules above as a starting point, there are many ways to increase your chances for a good contact, or at least hearing SAREX activity to qualify for a SWL QSL.

If you are using a directional antenna you need to know where to aim. A computer with a good tracking program that can handle orbital decay data is the best approach. Several programs are available through bulletin boards for free or as shareware. Some of the best programs are sold by AMSAT, the Radio Amateur Satellite Corporation (850 Silgo Ave., Silver Spring MD 20910; telephone: 301-589-6062).

Accurate orbital data is needed to give the program information to locate the shuttle and determine antenna pointing angles for your location. This data is commonly referred to as element sets. Due to the high and variable decay rate of the shuttle's low orbit, current element sets are a necessity. They can be found on packet radio bulletin boards, CompuServe, the Dallas Remote Imaging BBS (214-394-7438), the AMSAT BBS (201-261-2780), SPACELINK BBS at (205-895-0028) or from WA3NAN at the Goddard Spaceflight Center. WA3NAN operates on several HF frequencies during missions including 3860, 7185, 14285, 21395 and 28650 kHz. Most flights require accurate tracking data not more than two days old for accurate antenna pointing. If an omnidirectional antenna is used it is still a good

Photo A. Typical configuration "C" for SAREX voice and packet. (NASA photo.)

Photo B. End view of the Motorola SAREX HT shows channel selection knobs and other controls. (NASA photo.)

idea to know where the shuttle is located in the sky.

If you are aiming the antenna with an autotracking computer system, set the computer time exactly or slightly ahead, depending on how often the system updates the antenna position. For those with manual control, lead the shuttle by 30 seconds to a minute

to allow time for typing or calling as the spacecraft travels through the center of your beam pattern. Keep this up for the duration of the pass.

Be ready for voice or packet operation. The passes are short, usually about eight to 12 minutes. Antennas should be pre-aligned, receivers set to 145.55 MHz and transmitters set for

Photo C. Repackaged Heathkit TNC for SAREX operation. (NASA photo.)

144.49 (packet) or 144.95 (voice).

Additional frequency correction can be dialed in for Doppler shift. When the shuttle is approaching on a high-elevation pass, the received signal will be a few kHz high, so listen around 145.553 MHz. If possible, the transmitter should be set a few kHz low. This will center your signal in the receiver

on board the shuttle. When the shuttle is at its closest approach, there is no apparent Doppler shift so set both frequencies as listed. As the shuttle heads away, transmit a few kHz high and receive a few kHz low.

For packet operation set RETRIES=0. Many calls may be necessary to get through, and a timeout is

Figure 1. Pictorial of configuration "C." (NASA drawing.)

*EITHER FSTV MODULE OR CAMCORDER IS CONNECTED TO SCAN CONVERTER, BUT NOT TO BOTH.

Figure 2. Pictorial of SAREX system used on STS-56 for voice, packet, SSTV and FSTV reception. (NASA drawing.)

Photo D. Prototype of SAREX 70cm loop yagi for FSTV reception.

inconvenient. Other parameters may be adjusted for faster and more aggressive operation. Check the TNC (Terminal Node Controller) manual and experiment. If the SAREX TNC hears your call it will respond. Your system will register the connect and hopefully receive a QSO number. Your system

will then "ACK" back to the shuttle. The SAREX TNC will register the "ACK" and send a disconnect packet. Your system will respond and show "DISCONNECTED." If all goes well, your call will show up in the "QSL" list with a QSO number. If the complete contact was not successful, your call will be in

the "QRZ" or heard list. The SAREX TNC can capture and hold 650 stations in the "QSL" list, but only a few dozen in the "QRZ" list. It is up to the laptop computer on the shuttle to collect "QRZ" list data. Be sure to capture the data in your own machine for confirmation later since there is no guarantee that the SAREX laptop is on and collecting data. Beacon packets with the latest lists are sent every two minutes by the SAREX TNC.

For a voice pass use 144.95 MHz as the default uplink. Most operations on STS-56 and STS-55 earlier this year used this frequency. It is 600 kHz below the downlink on 145.55 MHz and can be used on all 2 meter FM rigs with standard repeater offset capability. Once again Doppler correction helps. If other stations are making contacts with the shuttle using the alternate uplinks (145.91 MHz, etc.)—try them. If the QRM on 144.95 MHz is fierce, the ham-astronaut will likely listen for signals on one of the other uplinks.

If you have an amplifier, use it. For packet, make one good contact and quit. The same goes for voice. Hundreds of stations are calling and multiple contacts or attempted rag-chewing won't help. A few hams have been known to make as many packet connects as possible for several passes. This inconsiderate activity makes it hard or impossible for everyone else.

It's a good idea to monitor as many

passes as possible, even after a successful QSO, just to practice antenna aiming and frequency tuning. The next shuttle flight might not be as easy.

If no activity is heard on 145.55 MHz, tune around. Scheduled contacts with schools or home may be taking place on unlisted downlinks. Early in a mission most passes are set aside for schools. Just listening to the astronauts' answers to questions from the school children is exciting. These kids may be future scientists, hams or even astronauts who got their first inspiration from the direct interactive conversation with an astronaut via SAREX. Don't even try to call if the downlink is not on 145.55 MHz. The SAREX Motorola HT uses much different uplink frequencies for these downlinks. The radio has 48 "channels" defining specific uplink/downlink pairs.

When a shuttle mission goes for an extra day due to bad weather at the primary landing site, or to allow more scientific studies, additional ham activity is common. The scheduled contacts are usually done and the ham-astronauts may have time for just "playing with the radio." A lot of good contacts have been made this way. The "big-guns" have made their contacts and are off chasing other DX on HF. Stations with less power or smaller antennas can usually get through with these conditions. Mobile stations and even those with HTs have had success. It's worth a try.

DIGITAL FIELD STRENGTH METER
FS 73
"SIGNAL CUBE"®

High Performance, Precision Instrument measures in relative and absolute units

- Relative measurements from 60 Hz to the GHz range and absolute measurements from 1 MHz to 100 MHz. (Broad band with no tuning adjustment).
- Adjustable length dipole antenna sets required sensitivity (At high gain settings, ambient R.F. fields from local sources will indicate on the display).
- Dipole antenna eliminates need for a counterpoise. (A single antenna type field strength meter utilizes the person holding the unit as the counterpoise).
- Consistent and repeatable readings can be obtained with the Nye Engineering unit since it is not necessary for the observer to hold or be in close proximity to the meter.
- A heavy duty cast aluminum, gasketed cubical enclosure is used. It does not easily tip over.
- The "SIGNAL CUBE" is factory calibrated to a standard for both absolute and relative measurements.

RTTY LOOP

Number 17 on your Feedback card

Marc I. Leavey, M.D., WA3AJR
6 Jenny Lane
Baltimore MD 21208

With all the traditional hoops and hoopla, I am happy to inform all of you that this column marks the beginning of the seventeenth year of "RTTY Loop." Believe me, it would not be possible, it would not even be thinkable, without all of your support.

In that regard, I appreciate the recent messages from Richard J. Molby and Tom Vicinanza (both via CompuServe), with their words of encouragement. Tom is looking for hands-on help in the Orlando area to help get his TTY machine online. Any takers?

Another CompuServe junkie, George F. Franklin W0AV, is looking for software to interface a TRS-80 Model 4 with a KAM TNC. George is one of a number of us who upgraded his business computer and is looking for a use for this otherwise-good orphan. Well, other than a modem communications package, I have no specific suggestions. Again, is anyone out there using such a combination?

That's the thing with RTTY—folks are always finding new ways to use old devices. For instance, Roger Owen WD8DJR of Eaton, Ohio, says that at one time he had an AEA PK-64 on RTTY, without much success. A short while ago, though, he found a used AEA CP-1 Computer Patch for a very good price and made the purchase.

"The CP-1 seems to be a very good RTTY modem, and I interface it with my Commodore 64 computer, which the CP-1 was designed for. So I have made a few RTTY contacts, but I can't say that I find much activity on any band.

"Twenty meters seems to be the most-used RTTY band but, of course, it fades out when I have the chance to

Amateur Radio Teletype

get on the air. (Isn't that always the case, no matter what mode?)

"The main objective in writing to you is that for those of us who can't afford a super whiz bang megabyte computer, with all the bells and whistles, and a RTTY unit with even more bells and whistles, I find the AEA CP-1 and Commodore 64 hard to beat. The problem I find, though, is that the CP-1 seems to be as scarce as hen's teeth.

"I use the CP-1 with a Kenwood TS-530S, and it seems to do the job. When I tried RTTY before, I found that the 530 did not have good filtering, so it was difficult to copy, mark, and space signals on RTTY. With the CP-1, the filtering is already built in. Hot dog, I'm now on RTTY!"

Roger's success should be a lesson for all of us. You don't need the latest and greatest to get onto RTTY. I know I have been saying this for quite some time, but it's a message worth repeating.

Some solve problems, others pose them. Henry Fales, Jr., of Orleans, Massachusetts, writes that he has "a friend who is a confirmed satellite QSOer. This guy has very elaborate radio equipment but is using a C-64 for tracking and decoding. Until now, the bit rate has not exceeded 1200 baud, so he has been able to get away with a C-64. Soon, however, things are going to change. The new packet satellites will operate at 9600 baud, and my friend will have to change computers.

"This person will not use a computer for anything other than amateur radio. Therefore, I would like the changeover to be as inexpensive as possible. Is it possible that a Commodore 128 could read and write ASCII at 9600 baud? If this were possible, I believe that he might be able to continue to use his disk drive and printer.

"I feel certain that an Amiga A500 could do it, but I hesitate to recommend a computer which is now an orphan. Please roll this around and let me know what you think. Perhaps there are readers of the column who are facing the same choice."

This is a problem with many low-end computers, Henry. The Radio Shack Color Computer is in much the same boat, with a significant upper limit on the speed of data communication. Personally, I would think you should be able to get an inexpensive PC compatible to serve, particularly if nothing too demanding is required of the thing. A used XT-style machine shouldn't set you back more than a couple hundred dollars, and might just include a hard drive, software, and other goodies. Shop around, and don't be surprised at what might be sitting in someone's basement.

Finally, here's a letter from Steven Petrecz N5WKL of Bossier City, Louisiana, asking a simple question that has a complex answer. Steven says that he is interested in starting to monitor RTTY on HF, and transmitting on VHF. He is in the process of building the FSK demodulators that are described in the Tab Books' publication 1001 Electronic Circuits, and he wants to build a video display, or "glass teletype," such as the HAL RVD-1005. He says that he does not want to use a computer as he feels he cannot justify such a purchase at this time.

Steven is looking for articles, books, and sources for parts for such an endeavor. No novice to construction, his ultimate desire is to build a basic solid-state RTTY station without having to resort to a computer.

At this time, this month, a complete answer to your question is really beyond the scope of this column. Over the past several years, several such terminals have been described in the pages of 73 Magazine. A search through the 73 index will show some built from discrete chips, and others from integrated circuits. There really are many ways to

skin this cat. The reason more of these circuits are not published now is that simple, cheap, and readily available used computers work better. However, that is no reason to abandon the older technology, if that is your preference.

So, if there is some demand for it, I'll see what I can do about abstracting or serializing a project like this. I hesitate to do it if there is only very limited interest, but I will gladly dive in if some of you let me know that you would like the information.

Remember that readers of "RTTY Loop" continue to have access to the vast collections of PC-compatible amateur radio programs. RTTY and amateur radio programs are in collections #1, #2, and #4. Collection #3 is a bunch of archiving and utility programs for both DOS and Windows. Each collection will fit on a 1.44 Mb, 3.5" disk. One or two programs may be lost trying to cram them onto a 1.2 Mb 5" disk, and you will need to send a whole bunch of low density disks, if that is your system requirement. Anyway, for any or all of the collection, send me sufficient media, a return mailer with sufficient postage affixed, and \$2 in US funds for each disk to be filled, to the above address. I am trying to turn these around within a few days so, if you have sent me a disk or disks and haven't heard in a reasonable period of time, drop me a note or an E-mail message to make sure I received the original package.

We'll try to get a schematic in next month for those of you with solder to spare and a hankering to strip some wire. One thing about this column, folks, is that you never really know in what direction we will go. Be sure to share your thoughts with me via mail at the above address, CompuServe (ppn75036,2501), Delphi (username MarcWA3AJR), or America On-line (screen name MarcWA3AJR). During our seventeenth year I will continue to address your questions and concerns about digital communication, from RTTY to computers, here in 73's "RTTY Loop."

A "Swiss Army" Foxbox

Hams who enjoy hidden transmitter hunting are some of the most creative people I know. Not only do they delight in finding devilish hiding places for "T-hunts" or "foxhunts," as these contests are called, but they are also creative in choosing and using radio direction finding (RDF) equipment.

"Homing In" regularly features hams who are pioneering new RDF devices and techniques. This month, the spotlight is on Marty Mitchell N6ZAV and Byron Garbrandt KD6BCH. If it's the second Tuesday or first Thursday evening of the month, Marty and Byron will probably be competing in the informal 2 meter "progressive" hunts in Orange County, California.

One participant starts a progressive hunt by activating his hidden T at 7:30 p.m. The first person to find it immediately sets out in search of another hiding spot and puts T #2 on the air about the time the last hunter finds T #1. Now everyone else, including hider #1, looks for T #2. The first finder of #2 goes out to hide T #3, and so on. The hunt continues until about 11 p.m., or whenever everyone decides to quit and head for a coffee shop.

Progressive hunts, sometimes called "leapfrog" hunts, are great practice for rapidly tracking down jammers and QRN sources. In order to participate you need your own RDF gear, plus a rig to hide when it's your turn. Since more than one fox may be active at a time, each should transmit regularly for only a few seconds, then be silent.

Marty and Byron set out to design an easy-to-use tone source and transmission cypher. Marty started with the versatile 8-bit HCMOS Motorola MC68HC705C8 microcontroller IC, which has on-board 8K ROM, 304-byte RAM, and I/O ports. He added ICs for RS-232 interface, tone decoding, and audio switching. Byron began writing the software.

Before long they had created a device that they decided to market. It is more than just a foxbox. It's a multi-function radio controller—hence its name.

The RaCon 6805

All you need to be the quarry for your club's next foxhunt is the RaCon 6805, a transceiver (mobile or handheld) for the hunt frequency, and a command transceiver (Photo A). You trigger RaCon to start transmitting or change its transmission sequence with dual-tone (DTMF) digits from the command radio's keypad. An intermittent-signal fox can be commanded on the hunt frequency by connecting RaCon's control input to the external

Radio Direction Finding

speaker/earphone jack on the hidden T.

Your callsign is permanently programmed into the microcontroller's ROM, as are nine transmission modes. They include three distinctive tone patterns and six on/off sequences, with transmit times from five seconds to four minutes. Dead times range from five seconds to one minute.

Preferences for foxhunt transmission sequences vary greatly across the country. For instance, in Southern California 15 to 30 seconds on, followed by an equal off period, is a popular mode. In some Midwestern and Great Plains states there aren't any big hills to reflect 2 meter signals or woods to conceal transmitters. To make the hunts more of a challenge there, rules often allow several minutes between fox transmissions.

To prepare for national distribution, Byron upgraded the firmware to accommodate these various local customs. In version 1.01, transmission mode #2 is user-programmable. With commands from your DTMF pad you can make its key-down periods as long or short as you want, with dead-time breaks from 0 to 15 minutes.

Mode #2 encourages you to unleash your creativity. You can use one or more of the ROM-programmed tone sequences, or invent your own. Key in up to 40 digits, each representing one of 16 tone pitches, and tell RaCon how rapidly to play them. With the right command sequence, RaCon will simulate sounds such as ringing telephones. Pseudo-random tone patterns are also on the menu.

Want to loan your RaCon to another hider? It's easy to change callsigns with a DTMF command. Worried about someone else accidentally or deliberately commanding your foxbox? Lock It with a DTMF command and RaCon will not respond to further commands until it hears its unique unlocking security code. (You cannot change the security code, so be careful about giving it out.) FCC rules prohibit auxiliary control links below 222 MHz, so if you're using the RaCon with a 2 meter transceiver, you must stay close to your hidden T so you'll be in "local control."

If you have a dual-band rig, the possibilities become more interesting. RaCon has a duplex mode, so you can command your dual-bander on 70 or 125 centimeters while it transmits on 2 meters. You can even play ventriloquist and talk through the hidden transmitter on the control link from your remote observation post.

By selecting the proper jumper configuration on the board, RaCon goes into the simplex or duplex fox mode when you apply power. Other jumpers select the proper PIT connections for various brands of handhelds and mobile rigs. RaCon requires +7 to +35

VDC at 33 milliamperes. Reverse supply polarity protection is provided.

Wait, There's More . . .

RaCon doesn't have to sit on a shelf between T-hunts. It has additional features that are useful around the shack. With a change of board jumpers or a command from your computer it becomes a DTMF decoder, a remote controller, a CW keyer or an automatic pager.

When someone makes a call on your local autopatch without identifying, you might be able to tell if it was a bootlegger and identify the culprit by decoding the number dialed. The RaCon board, connected to your computer's COM port, will do it. Digits received by RaCon's DTMF decoder IC are processed by the 6805 and sent to the computer in ASCII at 1200 BPS for display. In my tests, the SS1202 decoder had a wide audio level range and good performance even with noisy signals.

If you have an application for remote control by DTMF, you could write a PC

program to use the RaCon's ASCII output. For even more versatility, Byron has included a DTMF controller board with eight CMOS output lines on the data port. Tone commands set or toggle each bit individually. Return telemetry is provided.

The CW keyer function is useful for remote telemetry projects. RaCon converts ASCII letters and numbers from its RS232 port to MCW into your transceiver or an audio amplifier. Automatic push-to-talk keying during code transmission is included. You can set CW speed from 5 to 25 wpm with computer keystrokes.

With a one-line buffer, you can type ahead and have good-sounding code at 13 to 25 wpm. But if you use this feature to teach slow-speed Morse in your club's class, you'll have to time the character spacing yourself because Farnsworth letter spacing is not included. Byron plans to add it to a future upgrade.

The auto-page feature allows you to initiate telephone paging via radio with a five-character DTMF command.

Photo A. The RaCon and a dual-band handheld with high-capacity battery make a complete remotely-controlled station. Progressive hunt enthusiasts have found these foxes hidden in hedges, tethered in trees, and buried on beaches. (Photo by KØOV.)

Photo B. The RaCon 6805 circuit board measures 4" x 5-3/8" and mounts in the cabinet of your choice. Timing is crystal-controlled, so two or more foxes can go on and off in sequence, staying in sync for hours. (Photo by N6ZAV.)

RaCon stays at your base station, connected to a transceiver and a 1200 BPS telephone modem with the X4 result code set. By your radio command from the field, RaCon tells the modem to dial one of four pager numbers and send one of four messages to the receiving beeper.

RaCon ID's back to you via radio that the page command was received. You can command it to beep your own pager to verify that your page was successfully sent. Enter pager and message numbers into RaCon's memory with your computer and COM port. You cannot reprogram the four pager numbers and messages from the field via DTMF.

This would be a great use for your old 1200 BPS modem. (Doesn't everyone use at least 9600 these days?) I couldn't test this feature with my modem because it's so old it doesn't have X4 result codes. However, I know it

works because N6ZAV and KD6BCH regularly page each other on T-hunts using a RaCon and modem at Marty's house.

Three Hours Well Spent

RaCon is available in kit form only. Assembly instructions are minimal, but parts are easy to identify and component locations on the board are well-marked (see Photo B). Sockets for ICs are included, so you can test the board before IC insertion to accommodate firmware upgrades.

The unit that I tested had been assembled by N6ZAV. To get an independent view of the kit version, I questioned Mike Musick NØQBF, who bought one for T-hunts in St. Louis, Missouri. "As a fox, it's marvelous," he wrote back on CompuServe. "It went together in about 90 minutes, but I'm an experienced board stuffer. I'd guess that it would take a ham with more con-

ventional background about two and a half or three hours." Mike built his board into an aluminum box with a Yaesu FT-411E handheld and two 1.2 ampere-hour batteries. "I field-tested it with a friend yesterday and everything worked fine," he wrote. "It came right up with nary a hitch, took commands the first time, coughed up the chosen cycles right on cue, and went on its merry way. Very, very clean operation."

It was hard to find anything negative in Mike's assessment of RaCon, but he had one suggestion: "Connectors and controls are on adjacent edges of the board, so it makes a poor fit in typical aluminum boxes with U-shaped walls. I would have preferred all the connectors on one end."

The RaCon 6805 kit, including circuit board and all components, is available for \$79 from Marty Mitchell, 340 Otero, Newport Beach CA 92660. Add \$3 for shipping. As usual, this offer is

not guaranteed by 73 Amateur Radio Today or by me. You must supply cables and cable connectors for your radio and computer.

The RaCon is truly a "one-gadget-does-almost-everything" device. However, it has a few important limitations. RaCon performs only one function at a time. For example, it will not do DTMF controlling and CW keying at the same time. Select your mode with computer or jumpers at turn-on; cycle it off and on to change modes.

RaCon has no EEPROM. User-programmed call signs, tone sequences, pager numbers and so forth are lost when power is removed, and it reverts to ROM defaults. If you need user programming, be sure to provide battery backup to cover momentary power interruptions. A 9 volt transistor radio battery works fine for this.

When talking through your hidden transmitter in duplex foxbox mode, remember that the fox's carrier remains on until you command it off, since there is no COR and no time-out timer. Be sure to include a CW ID cycle in user-programmed tone sequences. (It is automatically sent in the ROM-programmed modes.)

RaCon, like all digital devices, has the potential for radio interference (RFI), both incoming and outgoing. I found that RF from a hand-held scrambles RaCon's brains, but only if the antenna is within inches of the unenclosed board. Putting the board in a shielded metal case should prevent RFI problems.

Marty is upgrading the 14-page instruction manual to include troubleshooting information and more detailed descriptions of the various modes. N6ZAV and KD6BCH are giving good telephone support to RaCon builders. They seek user ideas for improved and expanded RaCon functions.

Heard of a new product for T-hunters? Let me know about it so "Homing In" can review it. A T-hunting Buyer's Guide installment of this column is in the works for later this year. Write to my Fullerton address above or send E-mail via CompuServe (75236,2165) or Internet (JoeMoell@cup.portal.com).

Having Fun With Youth Forums

Now that the Dayton '93 Youth Forum is one weekend behind me, I can look back with a great deal of pride at the outstanding job done by all the youngsters who participated in it this year. A youth forum is one of the most effective recruiting projects for a club or radio organization, but you must be prepared and be willing to put lots of time and effort into it!

To a large degree, the preliminary work spent on getting the children and the event organized will determine how successful it will be. When preparing for a national convention, you should begin soliciting for articulate and accomplished young people months in advance. Most of the amateur radio publications will be happy to help you get

the word out if you give them enough advance notice. You should also take advantage of local club newsletters and school publications.

When getting ready for something as big as Dayton (I'm not sure anything else is), you'll want to attract children who will be at ease speaking in front of a large audience. I have found the recommendations of local hams to be valuable. Very often, the children they recommend have friends who are also licensed amateurs. Getting the word out on local repeaters is another good way to let folks know that you're interviewing young people who are interested in sharing ideas with other children and lots of other interested ham radio operators.

Contacting amateur radio equipment manufacturers is another important step to take. Let them know on official stationery that you will be conducting a youth forum. Advise them of how many people you

expect to have attending the forum, and be professional in detailing what your goals for the forum are. Yaesu, ICOM and Kenwood, along with AEA, MFJ and others, have always been generous in donating gifts or handouts to be won by youngsters attending these forums. At Dayton, Yaesu donated a 2 meter handie-talkie for the drawing at the Youth Forum. Let's be sure to support the manufacturers who are supporting educational efforts.

help available. There's no need to reinvent the wheel. Anyone contemplating a new youth forum or teaching young people should leave your forum knowing what to do next.

It is extremely critical that you spend time conversing with your prospective speakers at length. I try to get at least two phone conversations in before I make decisions. It's true that there is no fool-proof way to guarantee that a child

"Anyone contemplating a new youth forum or teaching young people should leave your forum knowing what to do next."

Next, it would be a good idea to contact the ARRL Educational Activities Department. Either Tracey or Rosalie will be happy to send you materials that you can distribute to interested teachers, instructors, and recruiters who will undoubtedly be attending the forum. Be sure to emphasize to prospective amateur radio teachers that there are lots of materials, books, curriculum packages and

won't get nervous or freeze up in front of a crowd, but you should be able to get a good handle on who is articulate.

Since all your speakers will probably be under 18 years of age, you should make it a point to introduce yourself to their parents. In many cases, parents will not be attending the convention and you will become the contact person for their child. Have all the information

INTRODUCING THE UNIVERSAL M-400

A totally new concept in code / tone readers!

- A RTTY-reader and tone-decoder in one!
- Easy to read two-line 40 character LCD.
- No computer or monitor required.

- Baudot
- SITOR A/B
- ASCII
- SWED-ARQ
- FEC-A
- FAX
- POCSAG
- GOLAY
- ACARS
- DTMF
- CTCSS (PL)
- DCS (DPL)

Forget the limitations you have come to expect from most "readers". The self-contained Universal M-400 is a sophisticated decoder and tone reader offering an exceptional range of capabilities. The SWL will be able to decode Baudot, SITOR A & B, FEC-A, ASCII and SWED-ARQ. Weather FAX can also be decoded to the printer port. The VHF-UHF listener will be able to copy the ACARS VHF aviation teletype mode plus GOLAY and POCSAG digital pager modes. Off-the-air decoding of DTMF, CTCSS (PL) and DCS is also supported. The M-400 can even be programmed to pass only the audio you want to hear based on CTCSS, DCS or DTMF codes of your choosing. The M-400 can run from 12 VDC or with the supplied wall adapter. The American-made Universal M-400 is the affordable accessory for every shortwave or scanner enthusiast.

Only \$399.95 (+\$6 UPS).

FREE CATALOG

This huge 100 page catalog covers everything for the shortwave, amateur and scanner enthusiasts.

Request it today!

Our New COMMUNICATIONS DECODER Is A MUST For All Serious FM'ers!

Introductory price: **\$199**

THE MODEL CD-1 DECODES & DISPLAYS:

- 104 DCS CODES (Digital)
- 50 CTCSS TONES (Analog)
- 16 DTMF DIGITS (Touchtone)

The CD-1 reveals everything you need to know to operate any open repeater or phone patch. Simply connect the CD-1 to your base, scanner or mobile radio.

When someone uses a system, the CD-1 decodes and displays the CTCSS or DCS code and in addition any DTMF codes that were used to control the system. (Including phone patch access codes and the phone number dialed). DTMF sequences are stored and automatically replayed just in case you missed something important. Use the CD-1 to learn police and fire codes too!

Prepare a list of all the children's names, callsigns, addresses, and a brief summary of their accomplishments. This should be handed out to the audience members so that interested people can contact the youngsters if they wish.

I always make it a point to call everyone involved with the forum a week ahead of time just to make sure there are no last-minute hang-ups. You might feel more comfortable if you have each child supply you with a copy of his or her presentation. When you call them for the final time you can offer suggestions about what they plan to say. Make sure that the speakers understand what you are trying to achieve with the forum. One of my main goals is for non-ham children to attend these youth forums and listen to upbeat and enthusiastic youngsters relate what it is that they enjoy most about amateur radio.

There's lots of work and preparation involved in organizing a successful youth forum, but it's worth every minute to be part of a well-spoken, highly accomplished group of youngsters who are indeed the future of amateur radio.

Be sure to come and say hello at my next youth forum.

available for them, such as possible airline discounts, hotel recommendations and other transportation arrangements. Many conventions offer the speakers free admission, banquet tickets, food scrip, or

other amenities. Check it all out ahead of time.

Make a check list ahead of time to anticipate the audio-visual needs of your speakers and yourself. Double- and triple-check with the

convention forum liaison person that all the equipment necessary for the youth forum will be available. Don't forget to check out the equipment ahead of time on the day of the forum.

The Ten-Tec Argonaut 509

Several months ago I described a home-brew classic, the Two-Fer. This month we'll look at another classic—the Ten-Tec Argonaut 509.

Even though this radio is slowly showing its age, it continues to be heard on all the bands, with the exception of the WARC frequencies. It has both SSB and the famous Ten-Tec QSK keying, making it a sought-after rig at hamfests.

One of the local hams called and asked me if I could look at his 509 because it would not transmit. After a few minutes on the phone to make sure that there weren't any misplaced wires or connections, we made arrangements for him to bring it over.

Since I have a 509 in my shack, I simply swapped out the plugs and connectors and replaced my rig with his. Turning on the power and setting the band switch to the proper position quickly proved that the receiver was very much alive and well. Several more minutes of knob-twisting proved that the receiver worked on all bands. So, switching over to the dummy load, I turned the mode knob to tune and adjusted the RF power control. Sure enough, the output meter just barely moved with the gain control fully clockwise. Yup! The transmitter was dead. Just to make sure the

problem was not only on one band, I tested the rig for transmit on all bands. Again, the RF output meter just barely inched up, telling me that the transmitter was indeed dead. Off to the testbench we went.

Fixing an Argonaut 509

The Argonaut 509 is easy to work on. You'll be flipping the 509 back and forth, so place something soft on your work surface to protect the case from scratches. A heavy bath towel works very well. Most of the case parts come apart to allow you access to the insides.

"Under no circumstances should you try to adjust the sealed coils (T1 and T2) on the receiver front end."

Start by removing the top case. There are two screws on the back holding the case top to the back panel. After the screws have been removed the top slides off. A small metal bracket holds the speaker to the top case. Release the speaker by removing the screw holding the speaker. The speaker will still be connected to the audio jack so be careful that you don't pull the wire either off of the speaker or out of the jack. After you remove the top, what you see is just the top half of the 509; the bottom is just about as full of modules.

The first thing to do is check for loose plug-in boards. When Ten-Tec originally installed the sockets for the plug-in modules they got a good batch. Unless you constantly plug in and remove a board, you won't see the socket wear out. I've never seen a bad socket in a 509. Still, let's not ignore what may be the obvious problem. The plug-in boards also have screws holding them in place. As I said, it's very rare to find a loose module in a 509, but check just the same.

The top half of the Argonaut 509 consists mostly of receiver boards and the control board. Looking down into the rig, with the front panel directly in front of you, you will see the control board on the right. On the left are the ganged tuned circuits for the front-end receiver; the low-level RF drivers for the transmitter are right under the cage.

Under no circumstances should you try to adjust the sealed coils (T1 and T2) on the receiver front end. You must have the proper test equipment to align these coils. You can't do it by ear, and you can't align them by watching the meter. In two words, "DON'T TOUCH!"

Without missing a heartbeat, I went directly to the PA, located on the bottom half of the 509. You must remove the bottom plate to get to the PA. There are several screws you must remove before you can get to the bottom of the rig. Notice what

screw goes where as which have machine threads and which are self-tapping. After the screws have been removed, slide the bottom plate off.

Right behind the large VFO box, toward the rear of the chassis, is the PA module. It's a plug-in module too, but the heat sink for the transistors is screwed to the main chassis. You must remove this screw to release the module.

I worked for a computer shop part-time fixing Apple computers way back when. Their service policy is outstanding. It went like this: "Try this . . . try that . . . replace the motherboard." So, having a second 509 at my disposal, the cheap and dirty way to check the PA was to swap it out with my known good unit. That's exactly what I did. After I tore apart my 509, I exchanged the PA modules.

Powering up the suspect rig, I plugged in a dummy load and flipped the mode switch to tune. Rats! I had just put in a known working PA module and there was still no power coming from the transmitter. So, not to be outdone by a simple problem like this, I installed the "dead" PA module in my 509, applied power, and the RF output meter swung up full-scale. It looked like the PA was good and there was something else wrong with the 509. Back to the testbench with another game plan.

The next step was to look for the proper T/R voltages. It's a simple test and requires only a VOM. Ten-Tec's manuals are very complete when it comes to voltage checks and circuit schematics for each module. All the needed T/R voltages are clearly listed. They are labeled "T" and "R" voltages on the schematics.

The T/R voltage must change when going from receive to transmit. It's a very sharp jump in voltage from less than 1 volt to about 10 volts. There should not be any voltage in between the two—it's either on or off.

Everything seemed to be fine, but since I had my 509 apart, why not switch out the control board. The control board generates the REF voltage for the VFO, along with the T/R switching voltages. This sounded good to me so I put my good control board into the dead 509. Again, no transmit with the new control board. I reinstalled the board I had removed from the dead 509 into my 509. It worked just fine. I then swapped the boards back, and guess what? My 509 wouldn't transmit. What started out as a simple fix had now killed two Argonaut 509s. For some people the birds sing!

Was there something in the rig that blew up my control board? Nah, the one I took out seemed to work just fine. But what could have killed my control board after I put it into the second rig? Well, first things first, and that meant fixing the transmit problem in the first 509.

I knew that the PA module was OK so lack of RF drive had to be causing the problem. The low-level drive comes from a non-removable PC

Photo A. Looking down from the top of the Argonaut 509. The right side of the photograph shows the control board. The large box in the center is the VFO compartment.

Photo B. The PA heat sink is shown directly below the VFO compartment. Notice the screw holding the heat sink down.

board deep down inside the receiver's front end. It's not easy to get to—this requires a major tear-down to accomplish. However, there is an easy way to check for proper operation of the low-level driver.

You'll need either an oscilloscope or an RF probe and VTVM (or high impedance VOM). Since both the low-level driver and the PA driver

transistors have their collectors connected to their cases, we can tell if there is any signal gain between the two. You'll need to remove the top of the receiver front end tuning cage. Be careful—you don't want to break any of the slugs or damage any of the coils. The cage will lift right off the top. Lay it aside for safe-keeping. Now, take your test probe

and touch the case of the low-level driver transistor. Set the scope to measure 0.5 volts peak-to-peak. Also, set your scope to read only RF and not DC voltage. Flip the 509 to transmit and slowly increase the drive control. You should see the RF voltage on the case increase. If you don't, that transistor or the stage feeding it is bad.

The next step is to leave the drive control where it is and move your test probe to the collector (case) of the PA driver. You should see a *large* increase of signal. Now, adjust the drive control and verify that the signal increases or decreases as you run the control through its range.

what? Four watts of RF into the dummy load. I still had no indication on the 509's meter, though.

And that's where we'll pick up next month, I'll finish the troubleshooting and tell you where the problem is and how to fix it.

If there is something special you would like to see here in the "QRP" column, please drop me a note. Perhaps we'll dig into a subject you would like to know more about. Who knows, we both might learn something when breaking new ground.

QRP ARCI

If you have been thinking of operating QRP and would like more infor-

"If there is something special you would like to see here in the 'QRP' column, please drop me a note."

If you don't see an increase between the two transistors, then either the PA driver is bad or something in between the two is shot. In my case, I had plenty of gain in both stages but still no output from the RF PA. So, I moved to the collector of the PA itself. Whoa! Plenty of RF coming out of this critter. What I did next should have been done days earlier—I connected up a wattmeter to the 509, flipped the mode switch to lock, and guess

mation about QRP and the QRP ARCI, you're in luck. I've just finished printing the new PR handout for the QRP ARCI. You'll get membership forms, a sample of *The QRP Quarterly*, and a short guide about the club and QRP in general. If you would like a copy, all you have to do is send me (at the address at the beginning of this column) either \$2 for postage or \$2 worth of stamps and I'll send a PR package your way.

How To Get Started In Packet Radio

Enter the exciting world of packet radio today with *How To Get Started In Packet Radio*. Dave Ingram, K4TWJ, wrote this beginner's guide to packet radio in an

easy-to-understand manner. It starts with a non-technical description of packet radio, followed by chapters that include getting started, setting up your station, networks, BBSs, portable and high-frequency operation and even a *Packet Radio Equipment Survey*. There's also an appendix that includes circuits for interfacing equipment. Join the most exciting and rapidly growing area of ham radio today! Order your copy of *How To Get Started In Packet Radio* book for only \$9.95! (plus \$2.00 S&H).

Simple Gray-Scale Generator

While at this year's Dayton Hamvention, I had the pleasure to meet with Mike Sheffield ZL1ABS from Auckland, New Zealand. He gave me a schematic of what has to be the simplest and cheapest source of video I've ever come across. Using just one CMOS logic IC, this circuit generates a beautiful gray-scale pattern which is perfect for adjusting monitors and TV receivers for proper contrast and gives you an inexpensive source of video for your ATV transmitter. This gray-scale generator is very compact and draws very little current—I used a 9-volt battery to power my circuit.

How It Works

The heart of the gray-scale generator is a 14-bit binary counter IC with an on-board oscillator (see Figure 1).

As the counter increments, a stepped output voltage is generated, thanks to the voltage divider network connected to outputs Q4-Q6.

When the counter activates Q7, the circuit resets and repeats the sequence. This reset signal essentially divides the 1 MHz clock frequency down to the video horizontal line frequency of 15,625 kHz (European standard). Keep in mind that we are not generating vertical sync with this generator, just a stepped voltage that repeats at the horizontal scan rate. The end result is a series of continuous vertical bars that increase in brightness from left to right on your monitor.

The NTSC Modification

Since this circuit originally appeared in the British Amateur Television Club's magazine *CQ-TV* (issue #138, p. 34; and #145, p. 74—Figure 1 is ZL1ABS' modified version) it was designed for the European horizontal line standard of 15,625 kHz (625 lines of video at a 50 Hz rate). The U.S. horizontal line frequency is

15,750 kHz (525 lines of b/w video at a 60 Hz frame rate). When using the circuit shown in Figure 1, you may have to adjust your TV set's horizontal hold to compensate for the different line frequency.

In order to generate a horizontal line frequency on 15,750 kHz, I searched the catalogs for an appropriate (and cheap) crystal. I finally found a 4.032 MHz crystal in the Digi-Key catalog. By increasing the divide rate by 4, you can now generate an exact NTSC output. Also, since 1 MHz crystals are quite expensive (about \$10), you save quite a bit by using the higher clock frequency). See Figure 2 for the NTSC standard gray-scale circuit. I added a 5 volt regulator to provide a steady video level if the supply voltage varies. The voltage regulator is optional as the circuit will work with a supply voltage from 4 to

12 volts. If you'd like to use this new circuit for European standard video, just use a 4.000 MHz crystal.

I hope you enjoy this unique generator. If you'd like to play with some variations of the gray-scale output, try moving the reset and voltage divider resistors to different divider outputs (I.e. instead of connecting them to output pins Q6-Q9, try connecting them to Q7-Q10).

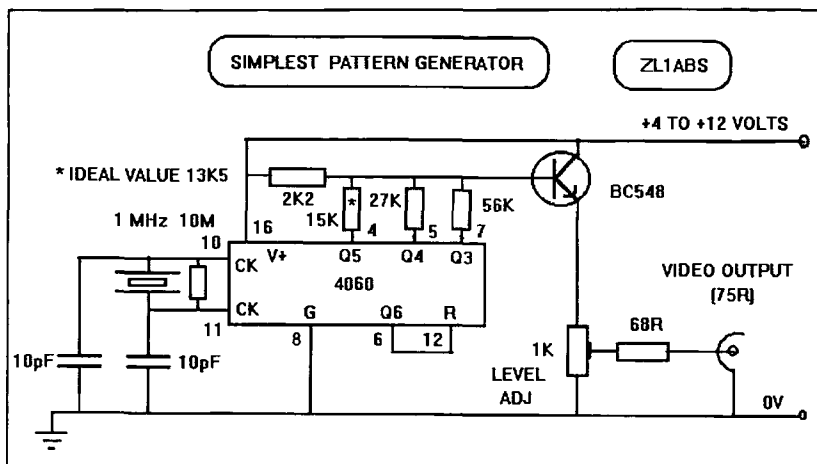

Figure 1. The original gray-scale generator (European line standard). Modified by Mike Sheffield ZL1ABS from circuits appearing in CQ-TV #138, p.34 and #145, P74.

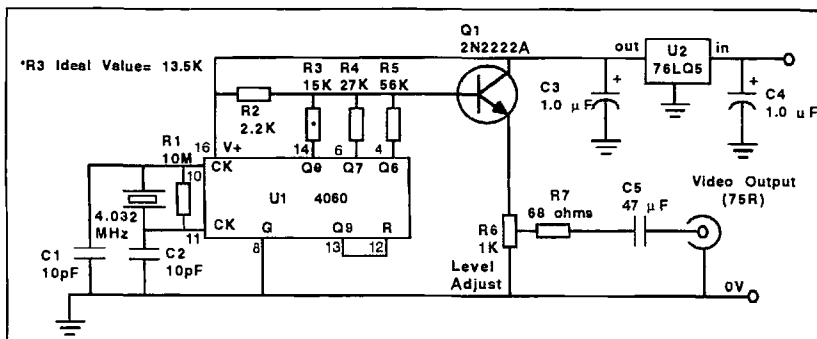

Figure 2. The simple gray-scale generator modified for NTSC U.S. video output (horizontal frequency of 15.750 kHz).

Figure 3. PC board foil pattern and parts placement for the NTSC version of the gray-scale generator.

HEIL SOUND LTD.

The SA-1 (near right) from Heil Sound, a new compact sound system for amateur radio receivers, will allow operators to hear weak signals, sort out the rare DX, and hear audio quality never before available to radio amateurs. The unit contains a high quality 5 watt amplifier and a 4" broadband speaker working into a ported acoustic cavity. A variable equalizer is built into the amplifier, allowing the operator to adjust the audio for maximum articulation. The extended response, added efficiency and additional power output from the SA-1 will lower your noise floor, increase articulation and allow you to copy signals that used to be impossible to hear.

The new PRO-SET (far right), is another entry from Heil Sound's continuing line of products developed by and for the amateur radio market. The unique qualities of this head-

set/microphone make it particularly useful for multi-op contesting and DXpeditions. It has an adapter type cable to facilitate dozens of connector pinouts for various rigs. There are three different PRO-SET models, with differences in the type of microphone element used. The vinyl earpad ring mount snaps into the headpiece for easy removal for

washing or replacement.

The headband is fully padded, with detent stops for each side. The unit is light but extremely rugged. The microphone boom is flexible and can be placed in just about any location, or can be folded up for traveling and storage.

The estimated retail price for the SA-1 is \$89.95; \$134.95 for the

PRO-SET. For more information, contact Heil Sound Ltd., Heil Drive, Marissa IL 62257; (618) 295-3000, Fax: (618) 295-3030. Or circle Reader Service No. 201 for the SA-1; Reader Service No. 202 for the PRO-SET.

TWT Power Amplifiers

This month I will cover the microwave amplifiers called "TWTs," or Traveling Wave Tube amplifiers. TWTs are the high-powered amps that were used for the moonbounce operations described in last month's column. The 10 watt units that I present here are somewhat lower power than the 28 watt type used by Charles Suckling G3WDG, or the very high-power TWT used by WA7CJO. In either case, the principles are the same but the higher power units are more desirable for moonbounce.

TWTs are the real holdouts for vacuum tubes in this age of solid-state design. The 10 watt TWTs (5 and 10 GHz) in commercial market use have been replaced by solid-state designs. However, in surplus they are somewhat rare. The very high-power devices still have many applications today and are used for satellite transmission both on earth stations and in space.

This month I'll look into the letter file, which is getting deeper due to the fact that I have spent most of my time recently on jury duty—I've been on a case for about five months. Needless to say, this is taking a toll on my amateur radio activities, but I should begin to take up projects again in a few weeks or so. There are so many different projects that I want to get into, but without adequate time I can't do them justice. I'll get back on the ball very soon; please bear with me.

The HP-491C

Jim N5TSP is in the process of building several stations for 1296, 2304, and 3456 MHz, using Down East Microwave transverters (check almost any issue of 73 Magazine for their advertisements). Jim writes that while he was in Southern California he ran across a Hewlett Packard HP-491C TWT amplifier rated at 1 watt output for 2 to 4 GHz operation.

He has several questions concerning the HP amplifier. First question: Do I know of anyone using these amps on 2304 and 3456 MHz? Well, Jim, I do not personally know of anyone using this amp but that does not preclude it from working well for you in this application. I use similar TWT amplifiers and they work quite well. The amplifier you picked up was originally intended to increase the output power from Hewlett Packard

signal generators (max 0 dBm) to higher power levels up to 1 watt for power applications.

Different generators require separate TWT amplifiers for their respective frequency ranges. Drive power for the TWT to put full output power (of 1 watt) is 1 mW or 0 dBm. They will also work "as is" in the FM and SSB mode of operation. The only modification involved is switching. That is because the units were intended to be manually switched on and off by means of toggle switches.

Second question: Can the power output be pushed up if it's being used in an intermittent duty cycle? Power output depends on a lot of things in TWT amplifiers. This type of amp is self-contained, with the high voltage regulated power supply inside the rack mount cabinet. Output power depends on tube condition and the precise voltage (+/-1%) on each particular element. Power can be increased by making adjustments to peak operation at a particular frequency vs. broadband operation. I would not expect to get much improvement (such as doubling output power). You might get 1-1/4 watt output at best. I suggest you leave it alone unless you want to experiment. What you get initially is about all you will ever get unless the power supply is out of adjustment. A small percent error here can mean a large microwave power output error.

Question three: Does anyone have documentation or info on modifications for the HP amplifier? On this one I will have to wait for help from our readers. I'll keep my eyes open. Our local surplus store has several of these amps for 10 GHz, but no manuals or even a schematic. If you choose to tinker with the unit, be cautious because the power supply for any TWT amplifier uses voltages in the several KV range. True, the current can be low, but the voltage is quite high and that is not only dangerous but lethal.

I hope this answers several questions. As a matter of general interest, these TWT amplifiers came in a series of units like the 491-C. The model 489-A works from 1 to 2 GHz, the 493-A from 4 to 8 GHz, and the 495-A from 7 to 12.5 GHz. Each unit works on different frequency bands from 1 GHz to over 12 GHz. For a low price, these units can make a good mid-power amplifier unit for base operations. All units in this series are rated to 1 watt power output. (Note: Drive requirements of the TWT are near 0 dBm/1 mW, making it drivable from a mixer or single-stage amplifier for

Photo A. 10 watt ITT power supply and TWT tube.

full output power.)

Many other manufacturers have made similar amplifiers. Hughes Aircraft made a similar unit to the HP-491, but these units are normally rated in the 10 and 20 watt level range. The TWT amplifiers that I am most familiar with are the ITT PW5C11C for the power supply, and the W3MC15C 10 watt TWT tube for 10 GHz. This unit is somewhat different; the power supply and tube are independent of each other and attach together by a single multi-conductor high voltage cable. A little terminology might be in order here. If the TWT unit is self-contained it is called an "amplifier." If it is separate (i.e., the tube is separate from the power supply), it is called by its component part names even though it is still a complete amplifier in all respects when connected together.

The ITT system that I use requires a DC system that is positive ground, negative 24 or 48 volts for operation. The ITT units were made in England so only surplus quantities of these units appear in the US. Far more popular, though, are the Collins Microwave units which came from Richardson, Texas. (Note: This source does not exist today.) Collins made this unit for the telephone industry, in which negative 24 and 48 volts is standard power.

I have several of these working units, and a couple more dead ones I rob for parts. Needless to say, this is the unit that Kerry N6IZW and I use for our 10 GHz stations. Originally, this unit was made to work in the commercial band of 10.7 GHz to 12.7 GHz. No re-adjustment is needed to operate on 10.368 GHz. I expect a little degradation in output power due to the lower frequency, but for the most part I ignore it. (See Photo A.)

Another manufacturer of TWTs is Varian Electronics in San Carlos, California. I have some of their units, but no schematic details. They are quite similar to the ITT units (positive ground), but do not require internal changes for DC input voltage variations. Both the Varian and the ITT TWT amplifiers operate on the

10 GHz band and have an output power of 10 watts. (See Photo B.)

Another TWT manufacturer is Thompson CSF Electronics. The unit that I have is a 6 GHz TWT very similar to the 10 GHz unit in that both power supplies were made to operate on 24 or 48 volts and positive ground. The TWT is external to the power supply. Again, this is a 10 watt unit. The Thompson model number is TH-21543 RM (rack mount), with a TH-3543 TWT tube. (See Photo C.)

Caution: Please note that while the Thompson and ITT power supplies look alike, they are not interchangeable. All tubes are keyed differently. However, they all have the same type of plug mounted on the end of their short cables. Don't let this cause you to make a mistake and use the wrong power supply with the wrong tube. If you try this you are in for quite a disappointment. Tubes and power supplies are all different and each requires its own special arrangement.

Part of the problem is that each tube requires slightly different voltages on elements of the TWT tube. Additionally, some of the tube elements do not come out on the same pins for all tube types. This is to help prevent the wrong tube from being connected to the wrong power supply. In most cases, interlocks wired into the tube socket prevent the power supply from being activated. But, according to Murphy's Law, it could be devastating at the worst possible moment. If you see such amplifiers in the surplus market, make sure of what you are buying. It might look all right connected up to the external tube, but CONFIRM THAT THE TUBE AND POWER SUPPLY ARE FROM THE SAME MANUFACTURER. I can't stress that enough! See Figure 2 for the DC power supply connections for the units described here.

There are solid-state alternates to TWT amplifiers. These units can take the shape of something similar to the satellite amplifier that I described in the September 1992 issue of 73. There I de-

Figure 1. 2 meter filter and added coupling arrangement.

Photo B. 10 watt Varian power supply and TWT tube.

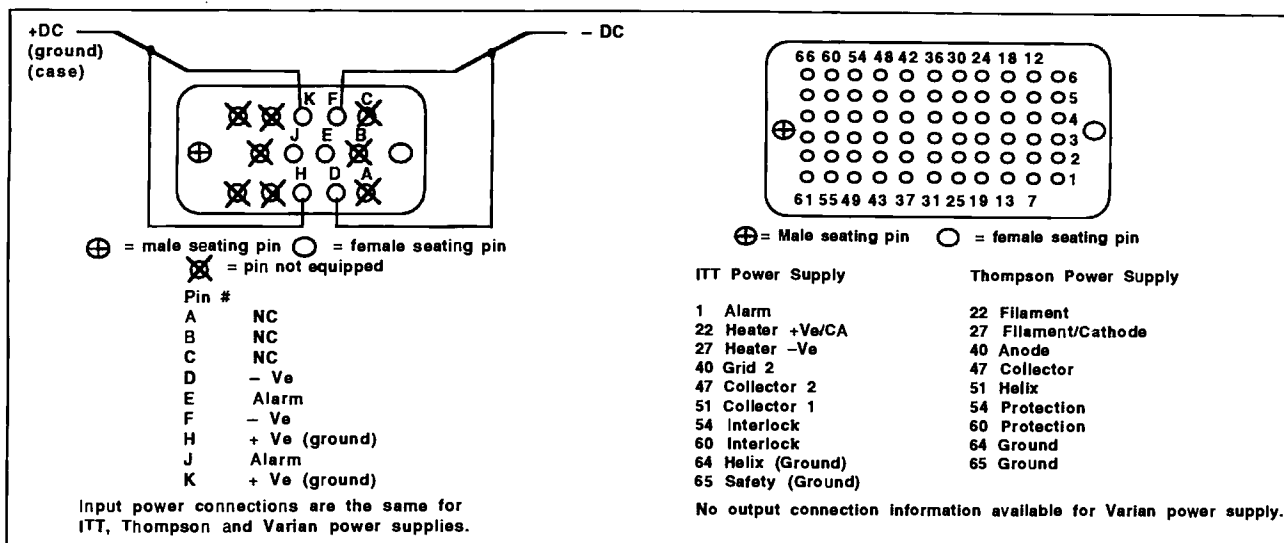

Figure 2. DC TWT power supply connections.

scribed converting a 1/4 watt solid-state amp from 14 GHz to the 10 GHz amateur band. I suspect that there will be quite a few devices similar to this unit, for many different frequency bands, showing up in the surplus market in the not-too-distant future.

Military surplus stores sometimes have some very good buys, but you'll have to really look carefully. If you're lucky you'll arrive just when the truck is unloading and get first shot at it. I've found several solid-state amplifiers, covering many different bands of operation. To date, I have gathered quite a collection of devices to aid construction of converters for several of our microwave amateur bands.

I consider some of these amplifiers as part of the class of hard-to-find materials I call "UNOBTANIUM." With military manufacturing in its current state of transition, I believe that there will be lots of new surplus material, including solid-state amplifiers. You've just got to keep your eyes open and keep a little cash tucked back in your wallet to take advantage of the opportunities when they arise. I'll get into solid-state amps next month.

Concerning the wallet, I was severely bitten by being \$20 short on a deal quite a few years ago. I don't think I will ever get over it. I missed out on a 2-cubic-

foot box full of RF power transistors at an auction due to 20 bucks! What made me so frustrated was that the material was in with some junk that went for peanuts and I was the only one who knew the devices were in that auction lot. I did my homework, but I didn't cover the financing. I have to chalk this one up to experience, for it taught me a very (expensive) valuable lesson. Oh well, you can't win 'em all.

Mailbox

Dominick N2LDJ states that he constructed two filters, the alternate spaced air coil and the variable capacitor filter (see "Filters for 2 Meters," "Above and Beyond," December 1992). "Although both filters work fine in removing intermod during receive, I can't tune up these filters on transmit. I am using an SWR/power meter to adjust and tune, but it appears that the filters on transmit are 'dead,' no power out. I have tried the methods to tune the filters as described in your article and have double-checked my connections, but still no luck. Help!"

Of course I will help. I believe that the spacing or coil-to-coil coupling might be too loose, meaning there's not enough coupling between circuits. As you state, they tune just fine on receive so the filters are peaking up in the receive mode. I suggest you add a coupling capacitor

between sections of the filters. This can be a small 2 to 3 pF capacitor, or even be a "Gimmick Capacitor." By gimmick capacitor I mean we form a capacitor out of a short piece of large diameter wire that is directly soldered to one of the tuned circuit's variable capacitor solder post and the insulated portion of this wire is brought in close proximity to the other coil. This, depending on position, will add the required coupling. See Figure 1 for a brief drawing detail on the added inner coil coupling.

Paul KB8CMW writes that I have provided lots of details on the Frequency West type of brick oscillators and covered some of the mods to these oscillators. "Do you have any information on the California Microwave bricks?" Paul states that he would like to get some information on modifying the filters. He is interested in tuning these filters for the 23 or 13cm bands. Paul is interested in any information on the retuning of this type of filter.

Well Paul, yes I have retuned these filters, but be assured these filters do not move very far from their original frequency. The lower the brick output frequency, the less the filter can be retuned. I use a rule of thumb that says most bricks can be retuned something like 5% of the original frequency. It's not exact, but in most cases it works fine.

On some rare occasions I have moved 8 GHz bricks to the 10 GHz range, but that is stretching the tuning to an extreme. All 8 GHz units will not tune that far, but some will.

I find it's better to retune, say, an 11 GHz brick to the 10 GHz range. This almost always works, except for broken or striped or locked tuning screws in the filter, making readjustment impossible. To retune almost any type brick you have to determine which filter type you have. Frequency West has two types: one with lock nuts on Allen screws, and the other with Allen screws on top (no lock nuts). To tune the one with no lock nuts you have to remove the diode multiplier filter portion from the brick top. The lock screws are on top and the tuning screws are inside the filter opposite the side of the RF output connector. To make adjustments on this type unit, the filter is reversed and placed back on top of the brick in a somewhat unstable position. The RF probe is placed back in the hole for RF drive to the filter multiplier. When it is installed this way, access to the adjustment screws is very easy. When it's complete, reposition the filter back in its normal position.

The adjustment procedure for the Frequency West brick that has the lock nuts is quite easy. All you have to do is build a special tool to relieve frustration. Take a nut driver to fit the locking nut and drill a hole through the handle to accept a small brass rod. To the end of the brass rod drill a hole to fit the Allen screw on the adjustment screw. Use the tool to, in one motion, loosen the lock nut and make adjustments with the brass rod/Allen wrench. These screws are under the top blue label.

For the California Microwave brick the procedure is somewhat the same as for the Frequency West brick without lock nuts. Unfortunately, it's a little tougher. The problem is that part of the RF output connector has to be moved in order to reposition the filter back on the brick. This enables you to loosen the top lock screws and gain access to the internal filter screws, all of which are very small Allen-heads. Adjust the frequency in small increments.

As always, I will be glad to answer questions related to this and other topics. For a prompt response please send an SASE. 73, Chuck WB6IGP.

The Scope of Things

Last time, we were discussing the ins and outs of oscilloscopes. Let's continue where we left off.

Double Vision

Why the heck would you want to see more than one waveform at a time? Well, as it turns out, it's incredibly useful. The basic structure of electronic devices is such that signals can be viewed in a series of stages. Each circuit stage does something to the signal inputted to it and then feeds it to the next stage. Some stages have several inputs, several outputs, or both. But the point is that any given stage changes the signal in some way. Perhaps it's a current amplifier. If so, it makes the signal carry more current so it can drive a bigger load. Or, perhaps it's a mixer. Then, it takes two or more input signals and produces a composite output signal.

A multiple-channel scope lets you see the input and output of a stage at the same time. Let's say you're looking at a voltage amplifier stage in the distorted audio amplifier of your 2 meter rig. The signal goes in and is supposed to come out the same, only bigger, right? So, you look at the input signal and, sure enough, it looks like audio. Then, you look at the output signal and, yup, it looks like bigger audio. So, the stage must be OK, right? Wait a minute. How do you know that the output's a decent replica of the input? Here's a great way: Connect one channel of your scope to the input, one to the output, and then turn the second channel's sensitivity down so that the waveforms are the same size on the screen. You should be able to superimpose them and they should look the same. If not, the radio's stage has significant distortion, which is just what you're looking for! (Actually, there's an even better way to use a dual-channel scope to find such a problem, and we'll get to it a little later.)

Another vital use for multiple channels is observation of the time difference between two signals. If, say, a circuit is supposed to delay a pulse by 15 microseconds, how do you tell if it really is working? By connecting one channel to the input and one to the output, you can actually measure the time difference between them. In fact, alignment of high-tech gadgets like VCRs and digital tape recorders is impossible without such measurements. And digital beasts like the frequency synthesizers in your radios often yield to such techniques, too. For that matter, any kind of phase shift or time delay can easily be seen and roughly measured.

How Many?

It is possible to make scopes with

just about as many channels as you want. Naturally, the cost goes up with each additional channel. Although you can buy quadruple-channel scopes, they aren't common. In fact, there are 8- and 16-channel scopes designed for digital work, but they cost two arms and a leg. Besides, you really don't need something like that anyway.

The most common kind of multiple-channel scope is the dual-trace unit. In fact, the 50 MHz dual-trace scope is a staple of modern electronics servicing. Let's look at how to use one.

I'd Rather Switch

Although some early dual-channel scopes actually had two separate electron beams in their CRTs, that was always uncommon, and it's unheard of today. Today's scopes have two traces, but only one electron beam. How do they do it? Just as you might expect . . . they fake it! There are two ways: One, the first trace is drawn and then the second, so fast that you can't see it happening. Two, the trace rapidly switches back and forth between the two traces, drawing bits of each as the beam sweeps horizontally across the tube. The first method is called an *alternate sweep*, and the second is called a *chopped sweep*.

Both methods work well, but each has advantages and disadvantages. Alternate sweeping becomes visible and annoying if the sweep speed is slow enough; one trace disappears while the other one is being swept. When using slow sweep speeds, the chopped sweep gives a much better illusion of having two simultaneous traces. Chopped sweeping, however, has the limitation that the chopping frequency (the speed at which the beam jumps back and forth between the traces) must be much higher than the horizontal sweep speed itself, or you'll see the chopping as a series of square waves, which, of course, is what it really is. So, you use an alternate sweep at high sweep speeds. Most dual-trace scopes let you select either method, but some do it automatically, depending on the sweep speed you choose.

There's one more way to see two channels at the same time: mixed together! Remember our discussion of the distorted audio amp? Well, what if we take the input and output, connect them to our channels and then mix the channels together? If we use the vertical amplitude controls to make them the same size, they'll exactly double, right? That doesn't do us much good, but what if we *invert* one of the channels? If you'll recall from last month, most scopes have a switch which lets you do that on at least one channel. Now, the signals should exactly cancel each other out, leaving a straight line! If they do, you know there's no distortion in the amplifier. If not, you can actually see the distortion products without the original signal, because you've canceled out what *should* be there! Pretty neat, huh? In practice, you do it

by playing with the output channel's variable amplitude control until the line is as flat as it can be. Whatever's left is the difference between the two signals, not counting their gross amplitude difference. Real circuits always show some difference signal, but you can get a pretty good idea from its size and shape whether it's reasonable or not.

It's About Time

I think we've covered just about everything vertical there is on an oscilloscope. Now we get to the fun part: time. At first musing, it would seem to be pretty simple. You select your sweep speed and you're done, right? Well, you can do that and, often, it's all that's needed. But, there's lots more and it's all pretty handy stuff.

Pull the Trigger

Before we get to all the neat things you can do, we need to consider one interaction between the horizontal and vertical domains. In order for you to see a waveform, it must have one important characteristic: It must repeat. Why? Because otherwise it would flash by and be gone before you'd even notice it. To be visible, the beam must trace over the same places on the CRT over and over. Unless you have some method of storage, such as digital memory (which we'll get to later), waveform repetition is an absolute must. (And, if you're looking at two signals at once, they must be harmonically related or one of them will be just a blur.) In the case of a sine wave, square wave or other simple wave, the point of repetition is obvious: once per cycle. But what about a TV signal or a digital pulse train? Such a complex signal may have all kinds of "cycles" within it and more than one point which could be considered the start of repetition. TV is a good example because it has vertical sync, horizontal sync, color sync, equalizing pulses and more, all organized into a big, long train which truly repeats only every other field! Finding the spot you want takes a good understanding of the entire signal. What's worse, depending on what you pick for your starting point, what you'll see can vary tremendously!

It should be clear that, even for the simplest waveforms, it is necessary to start the scope's trace at the same point on the waveform for each sweep. So how do you pick any spot to begin with? You use the scope's trigger controls. These consist of a variable knob and a few buttons. The knob varies the voltage point at which the trigger "grabs" the signal and starts the sweep. Generally, it's an uncalibrated control; you just turn it until the blur on the screen freezes. Usually, you can pull it out and reverse its slope, which refers to whether it grabs the waveform as it rises in voltage or falls. Doing that lets you start with a different part of the waveform, which may be just what you need in a given situation.

The buttons let you select how the signal is coupled to the trigger circuitry. They function in much the same way as the coupling buttons on the vertical channels. With DC coupling, you trigger on an absolute voltage level. Often, that's fine. But, if you want to

trigger, say, on a particular variation in a 100 mv signal that happens to be riding on 12 volts DC, you would be better off using AC coupling and blocking the 12 volts altogether. Some scopes offer low-pass and high-pass filters on the AC coupling. They are very nice because they let you avoid triggering on noise (with the low-pass filter) or trigger on a high-frequency component of the signal while ignoring its slower changes (with the high-pass filter). Ultimately, you use whatever gives you the view you need.

Some signals are so complex that it is impossible to trigger on them at all! No matter what you do, the trace keeps jumping around, making measurements impossible. Digital pulse trains are notorious for it. Some scopes have a *hold off* control which sets a variable time after triggering during which the scope will not trigger again, even if the trace is finished. This blocks some erroneous trigger points, but it often doesn't work very well if there are lots of them within the signal. The solution is to use a separate connection to some other part of the circuit which has a reliable signal for triggering. Most scopes make it possible by providing an external trigger jack and switch. Naturally, the signal you pick to provide your trigger must be synchronous with the one you want to view or you'll just get a mess on the screen. Luckily, many devices deliberately or incidentally provide such signals. In fact, the alignment instructions for many kinds of gear tell you where to find them.

Faster—No, Slower

Once you've got your waveform frozen on the screen, you can decide what to do with it. Here's where the sweep speed control comes into play. Calibrated in TIME/DIV, this control simply sets how long it takes for the beam to sweep across the screen. Set it faster and the waveform stretches out. Set it slower and it all squeezes together. Like the vertical amplitude control, it has a variable knob which must be set to its calibrated position for the marked times to be correct.

The calibration refers to the divisions, or boxes, on the graticule. If you set the knob to 2 ms per division, it will take 2 milliseconds for each box to be swept. Knowing that speed lets you do rough frequency measurements; just divide 1 by the sweep speed. Let's try it: You're looking at a sine wave which repeats every 2.5 boxes. (It really doesn't matter which point on the wave you pick as your starting point, as long as you pick the same one for the next cycle.) Your sweep speed is 2 ms/div. To find the frequency in Hz, just multiply 2 ms times 2.5, which gives you 5 ms (the time period of your waveform). Now, divide 1 over 5 ms, and you get 200 Hz. Of course, this method doesn't have the precision or accuracy of a frequency counter, but it does allow you to figure out the frequencies of intricate signals, including those buried within other signals, which is something no frequency counter can do.

Well, we're getting near the end of our oscilloscope tour, but there's still a bit more and I've run out of space, so we'll have to finish up next time. Until then, 73 de KB1UM.

HAM HELP

Number 24 on your Feedback card

We are happy to provide Ham Help listings free on a space available basis. To make our job easier and to ensure that your listing is correct, please type or print your request clearly, double spaced, on a full 8 1/2" x 11" sheet of paper. You may also upload a listing as E-mail to Sysop, to the 73 BBS/Special Events Message Area #11. (2400 baud, 8 data bits, no parity, 1 stop bit. (603) 924-9343). Use upper- and lower-case letters where appropriate. Also, print numbers carefully—a 1, for example, can be misread as the letters l or i, or even the number 7. Specifically mention that your message is for the Ham Help Column. Please remember to acknowledge responses to your requests. Thank you for your cooperation.

My antennas (VHF and HF) are installed at the top of a building, and to feed them I need 37 meters of coax cable. Presently there are two cables of thin coax. I am losing almost half of my power. I want to feed both antennas with only one coax RG8 and have a relay near the top to connect the antenna in use; or, match both antennas with coax cable. I need information on how to do this. Thank you for your help. Dawid Wahrsager PY1MV, Rua Santa Clara, 431 - Bloco 2 - Apt. 402, Copacabana, 22041-010 - Rio de Janeiro, R.J.

Wanted: Sony CRF 320/330; Panasonic RF 9000; Philips D 2999; Zenith Transoceanic, and the relative literature for each. Please advise regarding conditions and prices, including air mail costs. Send to Sabino FINA, via Cesinali 80, 83042 ATRIPALDA, Avellino Italy.

Wanted: Service Information or source for same, for automobile digital instrument clusters. Bill Molenhauer N2FZ, 136 Cedar Ave., Pitman NJ 08071.

Unemployed, newly licensed, Caribbean Ham seeking goodwill donation of ham equipment and related items. If it works I'll take it. No items too big or too small. I will make minor repairs. Age and external appearance not a factor. Jerry Aberdeen J39DF, Westerhall, St. David's, Grenada.

Needed: A pictorial guide and schematic for a Heath Kit Model HX-1681. I will pay for the copy and postage. George Therien KB1AHX, 20 Metcalf Ave., Centerdale RI 02911. Tel. (401) 354-6514.

Wanted: Manual or schematic for the Maverick Dual Power HF Amplifier. If you can help locate these items, please call Jim Hassen KB3ANX, (301) 422-1209.

Attention Hams: If you are using the Apple IIGS Computer for Packet, please write to me. Thank you. William J. Kerr, Sr. KA2KAN, RD3 Box 371, Everett PA 15537.

DSP NOISE FILTER

NEW!

LOW COST - \$149

Available Now!

Reduce noise and interference

- Automatic noise filter for voice

Eliminate heterodynes

- Multi-tone automatic notch filter

Razor-sharp audio filters

- 1.8, 2.4 & 3.1 kHz voice bandpass
- 100, 200 & 500 Hz CW bandpass

Simultaneously reduce noise, kill heterodynes, and filter QRM. Digital Signal Processing (DSP) technology provides unmatched performance in reducing noise and interference. Simply connect between your radio and loudspeaker. Enjoy cleaner, quieter speech and CW. **Money-back guarantee!**

Ask about our advanced model DSP-59 with over 300 filter combinations.

Factory assembled - high quality. **ORDER TODAY!**

Notes from FN42

This is another busy month with lots of great information. I'm sure that you would rather read about what is happening around the world rather than have me ask you to get involved. Instead, I will let our ambassadors tell you how they and others got involved.

We are lucky to have another ham step forward to let us know what is happening in his country. David Plett 3A2LZ has volunteered to keep us up-to-date on the happenings in the Principality of Monaco. I'm sure that you will enjoy his first of many submissions. 73—Amie N1BAC.

Roundup

Australia Downloaded from packet, WS10 @ W1EHD: IARU Region 3 Chairman David Rankin 9V1RH reports that Ron Henderson VK1RH, President of the Wireless Institute of Australia (WIA), has become a Silent Key. Ron died of cancer on April 26. He was an active operator and a good leader in administrative matters. His passing is mourned by amateurs worldwide, with condolences to his family, the WIA, and his many friends around the world.

Bangladesh From the Bangladesh Amateur Radio League (BARL) Bulletin: Finally, amateur radio activities from Bangladesh! S21A, Saif Shahid, the first licensed amateur radio station from Bangladesh, has now been on the air for more than six months and during that time he has made more than 5,000 contacts all over the world. Saif is active on 10, 15, 20, and 40 meters on voice and digital modes, including RTTY, AMTOR, and packet. Saif is also the president of BARL.

S21B, Nizam, is also regularly heard on 20 meters. He works mainly between 1300 and 1600 UTC on SSB and has made over 1,000 QSOs.

The BARL regular monthly meetings, the first Wednesday of the month, are becoming more and more popular. These monthly open forums are open to anyone who is interested in amateur radio and electronics.

Further information about BARL can be requested from BARL, GPO Box 3512, Dhaka, Bangladesh.

Kazakhstan Downloaded from packet, WB2DHY @ KC2FD: Beginning March 1, 1993, new call signs are being issued. They have

begun assigning a "UN" series of calls in several oblasts. This will continue throughout this year and all the "UL" series will be replaced. UL7 = UN7, RL7 = UN9, & UL8 = UN8. Kazakhstan is getting UN, UQ, and UP callsigns. UL calls will go to Uzbekistan.

Please make note of this information as more confusion will inevitably follow. I anticipate some serious frustration. 73 de Ed NT2X.

Sweden From the Sveriges Sändareamatörer (SSA) Awards Program: The SSA sponsors four different awards: Worked All Sweden Award (WASA), Heard All Sweden Award (HASA), Swedish Locator Award (SLA), and the Field Award. Both the WASA and HASA have classes and groups for HF, 144 MHz, 432 MHz, 1296 MHz, and satellite. The SLA will be issued to licensed radio amateurs for verified contacts made with the various Maidenhead locator squares in Sweden. All radio bands may be used and endorsements can be obtained for individual bands and modes. The Field Award will be issued to licensed radio amateurs for verified contacts with fields, as defined by the Maidenhead locator system. Endorsements will not be issued.

For further information contact: Sveriges Sändareamatörer, Östmarksgatan 43, S-123 42 Farsta, Sweden.

Ukraine Downloaded from packet, UB5LCV @ N8GTC.#CIN. IN.USA: The first Ukrainian International Hamfest, under the motto "Who is UB5?" will be held 21-22 August in Kharkov. The hamfest will include a Ukrainian Amateur Radio League (UARL) presentation, DXpedition reports, awards, contest information, a slide show, VCR tapes, and great cultural programs. Open forums will give everyone an opportunity to find out who we are.

Further information can be obtained from: Igor L. Zeldin UB5LCV, PO Box 4808, 310103 Kharkov, Ukraine; or, for those with packet: UB5LCV @ UB5LMJ. KHA.UKR.EU.

HONG KONG

Phil Weaver VS6CT
Flat 39C Two Park Towers
1 Kings Road
Hong Kong

Spring has arrived in Hong Kong after one of the coolest periods I can remember in 19 years here. It has also been one of the most disappointing periods of propagation that we have had since I first started operating amateur radio here in

1979. Periods of activity have been severely limited this winter by few openings and there hasn't been a lot of rare DX since last year's bonanza, when it seemed like we had new countries coming along every week, giving us more and more of that elusive Honor Roll status. I am one of the lucky ones! Having worked D, ET, FO, HKØ, SØ1, VP8, XE4, YA, ZA, 7ICENI/O, and 1SØ in the last 15 months, I have finally achieved Honor Roll status after 13 years of operating.

Fernando Nacedo Pinto, known when active a few years ago as CR9AK, is in the process of "folding his tent" in Macau to return to Portugal and retire, finally. He had planned to leave in December, and we managed to see him at the ELARCS Annual Dinner. A few days later a farewell party was held at the Yacht Club for his many friends from the many interests in which he participated, from motor racing to yachting to amateur radio. He is a fine example of someone who gave a lot to the hobby. Any ham was welcome in his home in Macau, and I remember doing two expeditions from "Fern's" house in the early '80s.

After nearly three years of negotiation and cooperation between the Telecommunications Authority and the amateur clubs in Hong Kong, we have just been advised that the New Amateur Radio License will be issued in the very near future, having been approved by the Executive Council last December. Considerable improvements, from the point of view of amateurs, have been introduced and many of the previous restrictions imposed have been relaxed. This is not the place to enumerate them all. Suffice it to say, I think we should be grateful to all the people who got themselves involved in this exercise and say "thank you one and all." A new credit-card-size operator's license will also be issued this year. This should overcome the difficulty of being stopped by the police when operating a handie-talkie on the street or if you have amateur radio in the car.

For those of you who are interested in visiting amateur radio festivals or expeditions (by whatever name) but cannot make it to the world's biggest, Dayton in Ohio, USA, I would like to draw your attention to the second biggest, which takes place each year in Tokyo Harumi district during the last weekend in August. I attended this festival once, in 1988, and thoroughly enjoyed it. We hope this year to have a group of Hong Kong amateurs to attend and if we can get a sizable group together, I am sure that we can get some interest in our visit from the JARL, who could probably lay on a party or two. If you want any further information about it, please give me a call at 887-6366.

ISRAEL

Ron Gang 4X1MK
Kibbutz Urim
D. Negev 85530
Israel

[The following are a few small tidbits from Ron. More will be published next month.—Amie] For the first time, the "Open University" has instituted a correspondence course for the advanced amateur license—the Class "A."

Packet radio continues to grow in popularity. 4X1MJ in Beer Sheva has made available kits for building the Baycomm modem, which can be put together for a very low cost. With the freeware program, the PC-clone computer takes over the functions of a TNC so that the TNC, an often hard-to-find and expensive commodity, is not needed. In the Beer Sheva area, thanks to Danny's efforts, quite a few new, young hams have been seen on the packet 4XNet.

Congratulations are due to Shlomo 4X6LM, who has completed his first year of editing HAGAL, the IARC magazine. He instituted many changes in the magazine, making it bimonthly and chock-full of technical articles, ham news, and more. The printing and graphics, coupled with the contents, have put the magazine in the first line of the ham publications in the world.

The Holyland Certificate Grid-Square collecting has become a serious mania! Those desirous of the squares should check the following frequencies: 14.265 daily at 1300 UTC, as well as 21.320 and 28.565. Many mobiles are active, putting the rarer squares on the air, and interest is running high. Saturdays on 7.050 MHz, there's great activity with the locals getting in on the fun. For further info on the award, check the back issues of this newsletter.

MONACO

Daniel Plett 3A2LZ
B.P. 349
MC 98007
Monaco

3A . . . JN33RR . . . 44 degrees 44 minutes North, 7 degrees 25 minutes East . . . Monte Carlo . . . These are all representative of the Principality of Monaco. Famous for its casinos and images of royalty and richness, Monaco is also well-known by amateur radio operators as one of the smallest and most rare countries to contact. Monaco is indeed quite small, one square mile to be exact. However, within this small area, there are about 50 licensed amateur radio operators.

The Association des Radio-Amateurs de Monaco (ARM) is the national society and has 29 members. The society's meeting place is open each Saturday for members to pick up or send QSLs through the bureau, check out recent magazines

Continued on page 82

73 INTERNATIONAL

Continued from page 80

from other countries, or just catch up on the latest news.

Here are a few bits of information to help you learn more about some of the distinctions of amateur radio in Monaco. All 3A1 callsigns are VHF only, no-code licenses. 3A2 callsigns are for stations with full operating privileges. Probably the two major differences in Monaco are that there are no 6 meter privileges at all, and that the legal limit for all stations is 100 watts. Due to space restrictions, most stations have limited antennas too.

Comments and inquiries are welcome. We look forward to chatting with you on the air.

OKINAWA

David Cowhig J76CBQ/WA1LBP
AmCon Naha
FBU PSC 556, Box 840
FPO AP 96372-0840

The coming of New Year 1993 brought New Year's greetings lasting throughout the month of January on the Japanese ham bands. Akemashite omedeto gozaimasu! If you plan to visit Japan, be sure to write the International Section, JARL, Sugamo 1-14-2, Toshima-

ku, Tokyo 170 Japan, about two months before you go for an application form. Once JARL receives your application, they will translate it into Japanese and send it on to the Japanese telecommunications authorities. Your license will be ready in about two weeks. The JARL does a great job helping foreign hams who come to Japan. The Japanese use the 144-146 MHz band largely for FM simplex and packet (in kanji characters and kana as well as alphanumeric characters) while repeaters (all-tone access—here in Okinawa mostly 88.5 Hz) are found on the 430-440 MHz band. You may need to modify your "made for the US market" handie-talkie to transmit in this range by cutting the right wire (and not the wrong wire, like I did).

In Okinawa, where Japan's spring begins, spring is starting its long northward trek towards snow-bound Hokkaido. Nago in northern Okinawa is now celebrating its annual Cherry Blossom Festival. Five Japanese professional baseball teams as well as two others from Korea and Taiwan began spring training in early February.

During our two-week-long Chinese New Year's visit to my wife's family at Bamboo Mountain (Chushan) in central Taiwan, I visit-

ed ham operator Jan Yigong BV5BR in his ham radio store in nearby Douliu. Mr. Jan's five-bay 2 meter antenna makes his downtown ham store hard to miss. Mr. Jan told me that the lower age limit for hams is 18, that the ham exam is given only once a year, and that since there is only one class of ham license, passing the exam (which includes an English language test!) is difficult. I told Mr. Jan about the US multiple-grade ham radio licensing system in the USA and about the Springfield Estates Amateur Radio Club started by Keith and Luke KO4IQ Ward in Springfield, Virginia, to show how young people can play a big role in ham radio [See the ARRL Education Workshop Proceedings 1991 for the story of this club]. Mr. Jan would like to see these things for Taiwan, too, but revising the Taiwan ham regulations will have to wait until the Taiwan radio world settles down.

Taiwan hams have had permission to set up repeaters since January 1, 1993. Although Taiwan hams have the 2 meter assignment of 144-146 MHz, they cannot use the lower 500 kHz of the band until the police move off it, perhaps sometime during 1993. There are college ham clubs in Taiwan at

Chenggong University and at Tsinghua University in Hsinchu. Mr. Jan explained to me that in Taiwan, hams (numbering about 2,000) are called huotui (hams), while their unlicensed brethren, the 300,000 or so xiangchangzu (sausage tribe), wander at will through various frequencies (they like 141 MHz best), in and out of the ham bands. Ham radio equipment is freely available and affordable in Taiwan so hams end up being much in the minority on the VHF and UHF ham bands. The HF ham bands are, in practice as well as theory, mostly reserved for hams. Fishing boats from Taiwan and southern Asia are often heard on 27-29 MHz.

The Taiwanese have been allowed to use radio transmitters only since martial law ended three years ago. Before then the only radio rule was that you were absolutely not allowed to transmit or possess a radio transmitter. The opening up of radio makes necessary a complex set of regulations which are not yet in place, although the Legislative Yuan of the ROC Taiwan government will probably make some progress on this during 1993. Taiwan hams regularly contact and visit in person their ham friends in the Chinese mainland.

ID-8 Automatic Morse Station Identifier

Compatible with Commercial, Public Safety, and Amateur Radio applications. Uses include Repeater Identifiers, Base Station Identifiers, Beacons, CW Memory Keyers, etc. Great for FCC ID Compliance.

- Miniature in size, 1.85"x1.12"x0.35".
- Totally RF immune.
- All connections made with microminiature plug and socket with color coded wires attached.
- CMOS microprocessor for low voltage, low current operation 6 to 20 VDC unregulated at 6ma
- Low distortion, low impedance, adjustable sinewave output 0 to 4 volts peak to peak
- Crystal controlled for high accuracy.
- Transmitter PTT output (to key transmitter while ID is being sent), is an open collector transistor that will handle 80 VDC at 300ma
- Field programmable with SUPPLIED keyboard
- Confirmation tone to indicate accepted parameter, plus tones to indicate programming error
- All programming is stored in a non-volatile EEPROM which may be altered at any time
- Message length over 200 characters long
- Trigger ID with active high or low
- Inhibit ID with active high or low Will hold off ID until channel is clear of traffic
- Generates repeater courtesy tone at end of user transmission if enabled
- Double sided tape and mounting hardware supplied for quick mounting
- Operating temperature range, -30 degrees C to +65 degrees C
- Full one year warranty when returned to the factory for repair
- Immediate one day delivery

Programmable Features

- Eight programmable, selectable, messages
- CW speed from 1 to 99 WPM
- ID interval timer from 1-99 minutes
- ID hold off timer from 0-99 seconds
- CW tone frequency from 100 hz to 3300 hz
- Front porch delay interval from 0 to 9.9 seconds
- CW or MCW operation

\$89.95 each
programming keyboard included

Data Communications

It's one thing to be able to talk and another to find out what to talk about. I'd like to see some sort of system where I could get a dump of subjects of interest to the chap I'm talking with. My computer would highlight anything of mutual interest, giving us an edge in starting a conversation of interest to both of us. We should be able to dump something like that in a couple of seconds. Work on it, okay?

Yes, I know we aren't permitted to mix packet and voice on the same frequencies, so we'll need to get some Special Temporary Authority (STA) permits to develop these multimode communications systems. You shouldn't have any problem getting the permits.

A New Day Dawning

If we can pull this off I believe this could completely revolutionize the amateur service. We'll be able to really build some international friendships. Special interest nets will start growing around certain frequencies. For the first time we'll be able to actually talk with each other instead of lecturing.

It's going to be a lot easier to get kids interested in hamming. We may even be able to get our growth rate back where it was 30 years ago!

We've got 100,000 ham channels sitting unused just on 10 GHz, so we could use a few more hams.

With our being able to talk in groups sharing channels we'll be able to handle substantially more operators on our HF bands. We may have to insist that the ARRL shelve its confounded DXCC award so operators in rare countries aren't swamped with walpaper hunters.

I would never say it, but there are those who claim that country hunters are trying to compensate for inferiority complexes. There are thousands of addicted ops who will fight the pile-ups for hours to get a five-second signal report from some damned rock sticking out of the ocean. I'd like to see their explanations to St. Peter about this silly waste of a life.

How Was Dayton?

Well, I had a good time . . . how about you? Oh, it was crowded. No, it was far beyond being crowded . . . it was packed solid. On Saturday there wasn't any way to get around. The exhibits had people stacked two and three deep, which left almost no room for anyone trying to get through the aisles. I got around as best I could, jumping up near each booth to try and see over the crowd what was being exhibited. I'd hoped to pick up literature, meet the entrepreneurs, and ask a lot of questions, but getting close

enough to talk turned out to be difficult.

Yet many dealers were complaining that sales were way down from last year. I did see a lot of stuff being carried from the flea market to cars, but not much in the way of new gear going that way.

There was an industry meeting on Thursday evening . . . run by CQ magazine. It turned out to be mostly a promotion effort for a series of professional hamfests they're planning. They seem to feel there's big bucks to be made in hamfests. Maybe. I guess the thing that puts me off is that hamfests haven't seemed to change much in the 55 years since I attended my first. Well, maybe they don't need to.

One motivation for the commercializing of hamfests seemed to be the lack of any regular hamfests in Northern and Southern California. With over a hundred thousand hams in that area, obviously (they opined) it should be able to support two yearly hamfests. Having attended quite a few California hamfests, I'm skeptical. In case you haven't been out there, California hams are different. They have shown that they are able to stay away from hamfests in huge numbers. Perhaps whatever weird psychological forces drove these strange people to move to California doesn't encourage them to seek the comfort of crowds. They seem to be a bunch of individuals, with little of the lemming-drive of Eastern-

ers to pile up into large human masses such as we see at Dayton, Boxborough, Atlanta and other such hamfests.

Armed with what seemed to be an instant statistic that 41% of all ham gear is bought at hamfests, the CQ team is going to try and organize the hamfest business. What's the "Q" code for "good luck"?

I Lusted.

I saw an awful lot of new equipment that got my juices going. Great stuff. Wait'll you get a load of the stuff AEA has for you. They've got a great SWR gadget that plots the SWR vs. frequency for you. At \$400 it's a bit pricey for most hams, but what a great gadget for clubs to buy and share. Once you see it, if you ever want to have your antennas working at their best, you're going to have to get one of these killers.

And of course their new packet contraption does so much that they should have a 10-hour video training course just to get you familiar with what they've crammed into that little box.

There were some fabulous new linear amplifiers that would look great in my shack. And maybe it's time to decide which new rig to get, and what kind of an antenna will give me a monster signal on 20m.

AUTOMATIC SIMPLEX REPEATER

THE SR-7110 CONNECTS TO ANY TRANSCEIVER TO MAKE A SIMPLEX REPEATER

- Portable or mobile repeater to increase the range of HTs
- Emergency repeater
- Test repeater to hear your own signal
- Test for skip conditions
- Unmanned hidden transmitter
- Calling frequency machine

The 7110 has two modes of operation. In the automatic mode the repeater only repeats when there is no reply to a transmission within two seconds. In the continuous mode all transmissions are repeated without delay. The 7110PL has a PL decoder so the frequency can be used without the repeater. SR-7110 \$200.00 SR-7110PL \$275.00

NEVER SAY DIE

Continued from page 86

And I Talked, Too.

For two hours! And it was only Sherry pulling my sleeve, reminding me that we might miss our plane . . . and the increased signs of frustration of the AMSAT bunch, who had the next stint in the room, that stopped me. What did I talk about? Oh, all this stuff I've been writing in my editorials, in my *Declare War* book, and *Declare War Updates*. I talked about my sneaky plan to get everyone off simplex and into duplex operation . . . a move which we should have made 50 years ago.

I talked about EMFs and cancer. I talked about how our cells communicate. And ecoscams; the plight of IBM and what could be done to save the collapsing giant . . . if anyone thinks Big Blue is worth saving. I talked about our basis and purpose (97.1) being totally obsolete, the stupid proposed VAT, deluding NASA and the superconducting supercollider, how America can make money on foreign loans instead of just throwing it away, and so on.

Oh yes, I also mentioned a huge coincidence that I've recently discovered. You're probably going to disagree with my take on this, but I'll tell you anyway. I've noticed that there seem to be almost no well-educated poor people . . . and almost no poorly-educated rich people. Now, it struck me that this may not be entirely an accident. Could there be a correlation between education and success? And if there is, do you think this might be enough to convince kids that education really is important if they're interested in not being poor all their lives?

Of course they may prefer to play the odds that they'll become successful performers, athletes, politicians, or clergy, where an education isn't critical. At least for a while. Then, how many rich boxers are there? How many rich ballplayers? Dozens. And how many rich business people? Millions. But is that enough to get people to think?

The cold, wet, windy weather drove the flea market scavengers inside, making it even more difficult to move around. It finally got to where it was no longer possible to talk with exhibitors . . . I couldn't get near 'em . . . so Sherry and I headed back to crowd-free New Hampshire.

I did enjoy meeting a bunch of old friends. Not having a booth this time gave me a lot more freedom to get around. I wore a 73 hat so people could spot me, but I found that no one looked at hats. Too bad, because I had it all decorated with badges and buttons . . . my submarine combat pin from WWII, my Royal Jordanian Radio Society (JY8AA) pin, my Korean Amateur Radio League (HL9WG) pin, one from New Zealand, one from China, Russia, and one from Poland. My hat was decked out like a CBer's vest at a CB picnic. No one noticed. Heck,

I even had a little gold hand key, my Old Old Timer's Club pin, and my old Boy Scout pin from the '30s. I used to have some pins for winning ARRL contests, but some ex-employee mercifully swiped 'em. Yes, of course I had my ARRL 50-year pin on there, right up front. And one from Erasmus Hall High School. Well, what on earth else could I do with all that memorabilia? Waste of time. It was invisible. Phooey.

The post office has been putting out some postage stamp pins, so I put on the 5¢ ham stamp, ugly as it is . . . and a Scott Joplin stamp pin, promoting the five Greener Pastures Joplin CDs I've put out so far. I put on a skin diving pin, but couldn't find any of my skiing pins. Just as well.

So I'll put the hat, with all the pins on it, up in the attic, and go bareheaded at future hamfests. You had your chance to admire my collection and you muffed it . . . all 30,000 or so of you.

Ham of the Year!

I was delighted to see that the Hamvention Ham of the Year award went to Harry Dannals W2HD. Harry and I go way back.

The main reason for giving him this prestigious award was Harry's getting the QCWA to support the no-code proposal . . . a change of heart on his part which amazed me at the time. That's what I would have expected of Harry Gartsman W6ATC, the previous president, for whom I have a ton of respect, but Dannals has been so steadfastly pro-CW all of his life that I was certainly surprised.

I first ran into Harry when he ran for ARRL Hudson Division Director in the '50s. I think this was when he became a big Wayne Green fan. He's been talking about me at hamfests and over the air to anyone who will listen ever since. I understand that now that he's retired all he does is sit and talk on a Virginia repeater day and night, mostly about me. I count him as one of my number one fans.

Harry's big aim in life was to be an ARRL director. I think his father had been one and he wanted to prove to his father that he could do it too. I remember his father, a true CW fanatic. I remember him diligently jamming DX phone ops on the low end of 80m with endless CQs. This is still one of the more popular aspects of our hobby.

When I worked with Chet K2EAF on the 1960 ARRL National Convention in New York City, Harry was the president of the Hudson Amateur Radio Council, which sponsored the show. Harry came across to many people as a small-minded, fatuous, ARRL apparatchik. I was there when he was elected to that position by the newly formed Council. He managed this coup by outtalking everyone else, even though he didn't really have anything to say. No, I was not jealous. I was busy starting 73 at the time, so running HARC was not an option for me. Plus, I was the president of the Porsche Club of America. I was just

amused that the deciding factor in who was elected turned on who talked the most, and never mind what they had to say. I filed that away in my mind just in case something like that ever came up where I wanted to be a club president.

After Mort Kahn W2KR retired as Hudson Division director, Harry grabbed that job. It was Mort, a retired millionaire, who was the brains (a term which obviously I am using loosely) behind the ARRL's "Incentive Licensing" fiasco . . . by far the worst disaster in the history of the hobby. Harry, a devoted company man, rose to the presidency of the League. I attended several of his talks at conventions and found no reason to change my early opinion of him.

I always admired the League's ability to overlook their rules against directors working in the communications industry when it came to Harry, who worked in the communications department of an aviation company. I got the feeling that they invoked that rule only when someone was running for director who had not come up through the League traffic-handling system.

I saw no signs that Harry had shown any signs of initiative while ARRL president, so his turn-around with the QCWA was an eye-opener. The new Harry was a winner, so I'm delighted that he's been honored by the Hamvention. I've known most of their award winners . . . such as Bill Pasternak WA6ITF, who wrote for 73 for years. Heck, he helped me move the magazine from Brooklyn to New Hampshire back in 1962. Another winner was Carole Perry WB2MGP, who writes our Novice column, and has had a profound impact on our hobby.

We ought to have more awards for outstanding hams. Naturally my twisted mind suggests that we should have both good and bad awards. We ought to have some way to honor Herb KV4FZ for his yeoman work in erecting an outhouse over 14,313 and giving amateur radio its biggest-ever black eye. And a posthumous award to W2BIB for his great work in jamming medical emergency nets. And let's not forget K1MAN, the man who rains on our parade with endless self-promoting blind broadcasts.

The good guys, like John Williams W2BFD, who pioneered RTTY; and Sam Harris W1FZJ, who showed us what could be done with moonbounce and invented the parametric amplifier, got passed by. How about Bill Hoisington K1CLL, who got a whole generation building UHF equipment?

Now that Harry has turned against CW, will we see the QCWA promoting no-code Extra Class licenses? That'll increase Harry's esteem even more in my tired old eyes. And if you're ever near Virginia please look for Harry and find out why he's such a devoted fan of mine. He's on the repeater day and night, so you can't miss him. But I do wish he'd take off at least a hundred pounds so he'll live longer and

thus be able to spread the good old Wayne Green word longer.

Reflecting The Recession?

Despite the crowds, many exhibitors I talked with felt that attendance was down this year. And I was surprised to find some areas where there had been exhibitors in the past, but were now sitting empty and unused. Apparently the recession has hit amateur radio. Well, it isn't going to be anything like the disaster of 1964, when amateur radio sales dropped 85% in one year.

As I explained a few months ago, it wasn't the recession that caused 73 to not have a booth this year. We looked at the sales figures over the last few years and found that most of the Dayton bunch were already subscribers. We weren't picking up enough new subscribers to pay for the booth, shipping the exhibit, plus a couple people to handle it. And I found that having a booth kept me from seeing as much of the show as I wanted . . . crowds permitting.

I'll be interested to hear from any exhibitors on how the show went. Was it profitable? If you're not sure how you can tell, use the same yardstick as you would for any other promotion . . . did you sell at least 10 times the total cost of the show in merchandise? And that's if you're making at least a 10% net profit with your product. If you're making 20% net, then you can get away with only five times the cost of the convention in sales to break even.

If sales are really down, this may turn out to be a poor time for CQ to launch a series of commercial hamfests.

Review: Universal Time Piece

What kind of a crummy hamshack doesn't have a large clock on the wall? Pathetic! No wonder I get so many QSL cards with the wrong time on 'em. Nitwits. Lids. You want a nice big clock that'll keep accurate. Further, since this is your hamshack you don't want just any lousy big clock up there. You want to cream your visitors with a high-tech scientific clock . . . one that will have them asking questions you can smugly answer, but which they won't understand. It's the only way to run a hamshack. You are an electronic genius and they are morons, and remember that. But please be kindly in your condescension.

The epitome of clock one-upmanship is the Spectra-Com WWV-format Universal Time Piece, available from JZO Research. This 10-inch colorful beaut deciphers the scratches, buzzes, bleeps, tones, clicks, and announcements from WWV. It tells you when to listen to get solar storm activity reports, which is something no bone-and-fried amateur can be without for more than a day. (Regular price, \$49.95; limited introductory offer, \$29.95; plus \$4.50 S&H. JZO Research, 7140 Colorado Avenue North Minneapolis MN 55429.)

PKT ELECTRONICS

PKT Electronics' PC Packet Station™ is a complete 2 meter packet amateur radio station on card for IBM compatible computers—simply plug in the PC, add an antenna and you're on the air. The PC Packet Station contains a quality Motorola 5 watt transceiver and a modem. It fits a standard IBM PC half-card slot and is compatible with both XT and AT computers. No external power is required. This is an ideal amateur station for computer users with the new no-code Technician Class license. There is no

significant RFI interference—Flexlam RF shielding and proper RF bypassing keeps RF out of your computer and CPU "noise" out of your radio. It comes complete with TNC software and a manual.

The PC Packet Station is priced at \$419 for a single channel and \$459 for a dual-channel unit. For more information, contact **PKT Electronics, Inc.**, 2668 Haverstraw Ave., Dayton OH 45414; telephone: (513) 454-0242, Fax: (513) 454-0242. Or circle Reader Service No. 205.

GORDON WEST

Amateur radio operators wishing to upgrade to Advanced Class may now obtain the 173-page FCC license preparation book written by well-

known instructor Gordon West WB6NOA. The Advanced book covers all 507 examination questions, four possible answers for each question, and West's unique explanations. The first 18 pages are devoted to bringing the licensed radio amateur up to date on recent changes within the Amateur Radio Service. Chapter 3 specifically guides the radio amateur through testing procedures for the Advanced Class exam. Gordon West covers each question including why the right answer is correct and offers tips on how to solve some of the Advanced Class math problems. West gives some formula shortcuts not found in any other publication.

The Advanced Class FCC license preparation book is available through most amateur radio dealers, or mail order from the W5YI Group at (800) 669-9594 for \$9.95. For more information, contact **Gordon West's Radio School**, 2414 College Drive, Costa Mesa CA 92626; (714) 549-5000. Or circle Reader Service No. 209.

LIGHTNING INDUSTRIES

MacRadio™ from Lightning Industries is an interactive study program for the new pool of FCC test questions for the Novice and Technician Class licenses. It contains all possible questions and answers that can be asked on a test. The questions and answers can be studied as flash cards or as practice tests. MacRadio's test generating function produces FCC-style examinations at the push of a button. The test can be taken on-screen or printed for use in a class-

room. MacRadio is fully compatible with the Macintosh System 7.0 and 6.07, and is shipped with a HyperCard 2.1 player. Minimum hardware requirements are the Macintosh Plus with 2 MB of RAM and a hard disk.

MacRadio is priced at \$29, plus \$3 shipping. California residents add sales tax. For more information, contact **Lightning Industries**, 1806 Milmont Dr., #125, Milpitas CA 95035; (408) 942-7998, Fax: (408) 262-5441. Or circle Reader Service No. 203.

CURRY COMMUNICATIONS

Curry Communications is offering two new products. The LF2A is a compact active antenna system for optimum low frequency reception in noisy environments. It features broadband coverage from 4 kHz through 450 kHz and more than 90 dB attenuation at 540 kHz. Low-profile and portable, it mounts easily to any pole or mast.

It virtually eliminates power line noise and hash, 10-element filtering eliminates AM/SW broadcast interference. There is substantial reduction in TV horizontal oscillator interference and light dimmer interference is eliminated.

The Model ANB-1089 receiving processor provides any long-wave receiv-

MILESTONE TECHNOLOGIES

Milestone Technologies has released Milestone LOGMASTER II, an update of the popular ham radio and SWL log-keeping program for DOS computers. The new version represents a complete redesign, incorporating a lot of changes requested by our customers, especially in the areas of the user interface, performance, contest operation and reporting. Milestone LOGMASTER and the CODEMASTER Morse training application have been continuously upgraded since their initial release in 1985, and this upgrade takes advantage of the latest compiler, database and processor technology. User control of the program has been significantly enhanced and there is a completely new user interface which supports (but still

does not require) the use of a mouse. A completely reworked database design allows for the maintenance of multiple logs for special purposes, such as DXCC and contesting, and the number and size of logs is limited only by the available disk storage space. A key feature is ease-of-use: Anyone who can keep a paper log can use LOGMASTER straight out of the box.

LOGMASTER II is priced at \$29.95. Current users of LOGMASTER can upgrade for a nominal handling charge of \$10. For more information, contact **Milestone Technologies**, 3140 South Peoria St., Unit K-156, Aurora CO 80014-3155; telephone: (303) 752-3382. Or circle Reader Service No. 204.

DOUGLAS RF DEVICES

Douglas RF Devices has released a PC board and component kit for the Roanok Doppler DF Unit featured in *Transmitter Hunting—Radio Direction Finding Simplified* by KØOV and WB6UZZ. This unit offers the same

ease and flexibility of use as other systems costing 10 times as much. The Roanok Doppler DF Unit features a 16-LED circular indicator which provides 22.5 degree resolution which is quite adequate for mobile use. The kit comes ready-to-assemble, with over 95% of the entire project on the PC board and it can be assembled in about an hour.

The board and component kit sell for \$87.50 postpaid; *Transmitter Hunting* is \$19.95 plus \$2.90 shipping. Enclosure kits and antenna array kits will be released soon. California residents add sales tax. For more information, contact **Douglas RF Devices, P.O. Box 246925, Sacramento CA 95824-6925**; telephone: (916) 688-5647. Or circle Reader Service No. 206.

er with improved flexibility and reception capabilities. The ANB-1089 features: a selectable 20 dB gain preamplifier; a 15 kHz bandwidth filter; automatic noise blanking (threshold adjustable); adjustable IF shift; continuous coverage from 10 kHz to 450 kHz; and a connection for oscilloscope monitoring of noise blanking. It's ruggedly built, small, and portable.

The LF2A is \$155 ppd.; the recom-

mended collapsible 60" stainless steel antenna is \$13; and additional 25-foot interconnecting cables are \$6 each. The ANB-1089 is \$108.52. California residents must include sales tax. For more information, contact **Curry Communications**, 737 North Fairview Street, Burbank CA 91505; (818) 846-0617. Or circle Reader Service No. 207 for the Model LF2A; No. 208 for the Model ANB-1089.

David Cassidy N1GPH

First QSOs

Almost every ham has an elmer in his or her past. I had several, mostly the faculty advisors and other members of the Brockton (Massachusetts) High School Amateur Radio Club. Somewhere buried in a box are the high school yearbooks that contain the names and pictures of these elmers, but I can't for the life of me remember their names off the top of my head. Maybe I ought to dig out those old books.

I remember my very first QSO under my own call sign. It was with a station in Dallas, Texas, and I don't even have to look in my first logbook to tell you that it was on the 15 meter Novice band. My call sign at that time was WN1UIR, soon to be changed to WA1UIR when the FCC stopped giving Novices the special WN prefix. Since I was operating from a fellow radio club member's home station, I dutifully signed WA1UIR/1, as was required at the time.

Like probably hundreds of thousands of other first QSOs, mine was made on a Heathkit HW-16. For those of you who have never had the pleasure of a QSO on a HW-16, I pity you. To my 14-year-old eyes, it was the embodiment of wonder and adventure. It's dial lighting emitted a soothing glow in the dark, cool basement of my friend's house. The matching VFO allowed us access to the entire Novice HF frequency allocation.

My friend made a few contacts, and I copied along. Finally, he turned the straight key over to me and said, "Go ahead... give it a try." I tuned around and found an open spot and committed my first act of RF emission.

"CQ CQ CQ YQ CQ YQ DE WN1UIR..." Oh, no! What's a slash? OK, OK... I got it... "1 WN1UIR/1 WN1UIR/1 K..."

Almost immediately, I heard my very own call sign coming through the speaker of the HW-16 at approximately the same speed I had been sending, which was, of course, about three times the speed I could copy. I got as far as WA5, then froze. Luckily, my friend was copying along, and he quickly showed me the station's call sign circled on the top of his piece of paper. Phew!

I sent both call signs, then imitated the few QSOs I had watched my friend make. I sent my name, QTH and signal report. I also managed to say that it was my very first QSO, then sent "HW CPY?" and both call signs again. After the KN, I quickly grabbed my pencil, determined to show my friend that I had actually passed the Novice code test.

"FB DAVID—NAME HR IS BILL. BILL—QTH IS DALLAS DALLAS—UR RST RST IS..." Jeez, this is tiring! Ohmageddoo, I hate numbers! What was that? Did you get that? He's speeding up! Calm down... Calm Down!... CALM DOWN!! Forget about what you missed. Just start copying again.

"SB—SO BK TO YOU DAVID - WN1UIR/1 DE WA5..."

My friend quickly showed me his perfect copy, filling in the halt that I had

missed. My RST was 569, with QRM and QSB. What was that? Oh yeah... I remember... interference and fading. OK... my turn again. Gee, my hand hurts!

"... DE WN1UIR..." What was the slash? I forgot the slash! Oh, yeah, "... /1—FB BILL—SLD CPY HR—" Now what do I say? I have absolutely nothing to say to this guy. Maybe if I just shut the rig off he'll think I had a heart attack or something. Or maybe he'll spend the next few days fruitlessly calling WN1UIR/1, finally turning my call sign over to the FCC as a rude and shameless example of a bad amateur radio operator. I'll lose my license. I'll be fined... thrown in prison... my Dad will lose his job and my family will be ridiculed and scorned!

My friend saved me from this dreadful fate by suggesting, "Why don't you tell him what rig you're using, then tell him that you're operating from a friend's house? Since you're not in the *Calbook* yet, you could tell him you really want his QSL card, then send your address. Then, maybe mention the nice spring day we're having. Tell him how old you are, and that you got your license at your high school radio club."

Great ideas! I launched into a 10-minute monologue mentioning each and every one of these things. I always found it much easier to send CW than to receive, so I had no trouble banging away, though I lost my place a few times and I'm sure I misspelled a few words. After finishing my life's story, I turned to my friend and asked, "Now what do I do?" "How about letting him talk for a while," he helpfully suggested. Darn, that means I have to copy again. Oh well, I guess there's no way to avoid it. I sent the call signs and grabbed for my pencil.

There were at least three other CW signals coming through the speaker now, none of which I could copy. My friend said he had our station, pointed out which one of the CW signals was the WA5's, then we both struggled to copy the fading signal:

"... QSB... QSL OK... SAY 73 73 ES... AGN... DE WA5..."

Now what do I do? I didn't get any of that! I can't respond if I don't know what he said!

My friend calmly explained that my WA5 was saying good-bye, and that I should tell him that the QRM and QSB were getting worse, thank him for the QSO and say 73... which I did like an old pro (if I do say so myself).

That was it. My first QSO. I was officially an amateur radio operator. We looked up Bill's address in the *Calbook*, and I sent out my first QSL card, writing "Trx for my first QSO!" on the back. A week or so later, a glossy black QSL card with silver printing showed up in my mailbox.

Since that day, I've had thousands of contacts using many different modes. Most of them are just letters written in a logbook, but I'll always remember that first one... and the patience of my friend and that ham in Dallas.

A few years ago I had the privilege

The summer doldrums... you're probably tired of hearing that by now. July is not considered a particularly good month on the HF bands because of the high QRN levels and the high absorption of signals surrounding midday. However, short skip will prevail on some bands during daylight hours, and there will be reasonable DX in the mornings and afternoons (local time). Here's what you can expect for general conditions.

10 Meters/12 Meters

Some north/south DX paths open in the afternoon. Short skip out to 1,200-1,500 miles should be good on most days (calendar symbol "G," "G-F," "F-G").

15 and 17 Meters

There will be fairly good DX to countries below the equator during daylight hours (only on "Good" days), peaking during the afternoon. During the day, there will be good short-skip and sporadic E communications out to about 1,500 miles (for example, some east/west paths to Africa on "Good" days).

20 Meters

This is the DX band of choice during July, and worldwide DX can be expected on days marked "Good" (G) on your calendar. Best conditions during the day will be shortly after sunrise and shortly after sunset, although the band will stay open after dark. Excellent short-skip openings will take place throughout the day.

40 and 30 Meters

Evening, nighttime and early morning hours will provide DX on the "Good" (G) days. Around midnight the DX will be toward Europe; just before sunrise it will be toward Oceania and the Far East. Short skip will be excellent during daytime. As always, thunderstorm activity and high noise levels will dim the results on some days.

80 and 160 Meters

Neither band will show much

daytime activity because of the high absorption of signals. Nighttime DX will depend on atmospheric noise levels (QRN), but you can expect some DX on the "Good" (G) nights. Short-skip will prevail on 80 during the day and night, with nighttime short skip out to 2,000 miles or so. You can also find short skip out to 1,000 miles or so during the night on 160 meters.

Using the Calendar

The last week of the month is expected to be the worst for operating, with the 28th through the 31st being particularly poor. For best conditions look at the "Good" (G) days and for trends from "Fair to Good" (F-G). It is possible that severe weather and other geophysical phenomena will take place on or around the days marked "Poor" and "Very Poor." Batten down the hatches and be alert for warnings around the 28th-30th, the days marked "Poor" and "Very Poor."

NEVER SAY DIE

Wayne Green W2NSD/1

The Ugly Americans

No, we don't have a complete lack on being ugly, but we sure are way out ahead of whoever is in second place. Our recent and successful effort to chase His Majesty King Hussein JY1, the most famous ham in the world, off our bands with catcalls and name-calling is one of which all Americans can be proud. We can also point with pride to our continuing stupidity on 14.313.

One does not have to visit very many countries to find out what kind of reputation Americans have. The lack of consideration we exhibit in chasing DX is something they see in most American tourists, too. They claim we make up in arrogance what we lack in education and culture.

We tend to come across as unintelligent, but it isn't that. I'm convinced it's our educational system. Indeed, if you've taken the time to find out about IQ and IQ tests you know that (a) Asians have a several-point lead on whites in IQ, and that (b) American blacks tend to have a 15-point lag. You also know that (c) few journalists have bothered to learn the well-documented facts before writing on this emotionally-charged subject.

Alas, there's far too little correlation between having brains and using them. A computer is pretty useless when some of the keys are out of action and the programs have too little data with which to work. Well, the same goes for our brains. If we load them down with garbage, it's the old computer cliché: garbage in = garbage out.

So here we are with an educational system dumping garbage into little minds. We make up for that by virtually cutting off all intelligent communication with our kids, trusting them to learn how to interact with people via what they're watching on TV. Perhaps we deserve what we get.

No, I don't agree with King Hussein's support of Saddam. But I understand the fix he's in, with a large part of his people being Palestinians and being sucked in by Saddam's propaganda . . . plus a bunch of wishful thinking. I doubt any of us would have done as well as His Majesty under the circumstances. He's treading a tightrope over a tinder box, to coin a combo-cliché.

Of course, I'm critical of HM's getting into this fix. I think he could have avoided it. He's in trouble for the same reason we are . . . he's allowed a really terrible educational system to develop. I know you're going to find this difficult to believe, but Jordanian kids are even stupider than American kids, and it's got nothing to do with their basic intelli-

gence. Our kids come out next to the worst in surveys. Only the Jordanian kids have managed to beat us out of last place in international comparison tests.

His Majesty has done a lot of good things for Jordan. But he's been so involved with Mideast politics that he's let some very important things slip through the cracks. In addition to re-inventing the Jordanian educational system, he also needs to put some effort into eliminating graft as a means of getting rich and put more emphasis on rewarding people who are working hard to improve the business climate.

He had a wonderful opportunity to provide leadership and help to the Palestinians in Israel by providing educational programs in Arabic on his TV stations and beaming 'em into nearby Israel. During the Intifada the Israelis closed the Palestinian schools. This seemed like a really dumb approach. It's ignorance that's the main enemy in that part of the world. About the only benefit to ignorance anywhere is the ability it provides to those with an education to take advantage of the ignorant.

Jordan has no natural resources of value, only its people. Thus, the more His Majesty invests in his people's education, the richer his country will be, and the better the legacy he will leave.

Several years ago I tried to convince HM of this, pointing out the potential Jordan had to become the educational center for the whole Arab world. Once they started broadcasting educational programs on TV they could also package them on videotape and easily repay the production costs. What courses? I had in mind everything from preschool on through to Ph.D. graduate courses. I had in mind courses helping people to learn special skills. Engineering, architecture, business, ecology, nutrition, astronomy, medicine, and so on. No, many of these won't eliminate the need for a live teacher, but they would make it possible for live teachers to reach a much wider range of pupils.

This approach to teaching will even work well with cooperative learning, where students work in teams and teachers are cheerleaders instead of instructors. This is a relatively new approach to teaching which is winning converts all around the world. I cover this in my book (*Declare War*), so I won't go into detail here on how it works.

What Can We Do?

The first step is to throw some light

on the jerks who are devoting their lives to ruining our hobby. This means we need to get good at locating these ham terrorists. The FCC has some very sophisticated direction finding equipment these days, so I'd love to see some articles on how we can build what it takes to find these jerks.

I've already explained in the past how we can identify any individual transmitter just by its characteristics. Every rig has a slightly different fingerprint. All you do is record it and expand the starting edge of a transmission and you'll see that no two are precisely the same. We need some articles on this technology. As far as I know this stuff isn't classified, so let's see some articles.

Once we find out who these jerks are we can throw the spotlight on them and watch them scurry for cover, like the stinking roaches they are.

What better activity for a radio club than helping to clean up our hobby? We're supposed to be self-policing, so let's get our act together and deliver on our promise and stop calling the FCC and whining every time we have problems.

We can clean out 14.313 in short order if we really want to. And ditto any other festering sores that boil up.

If You Hear HM . . .

Tell him Wayne will be glad to come over and help get his educational system out of the cellar. I haven't visited Jordan in years, so it's about time I wandered over that way. Jordan is ideally located to help eventually solve the Israeli-Arab mess, as well as to stop the move to Muslim fundamentalism which is even a greater danger in the long run. All of these problems can be solved with education. But then, that holds for all the rest of the world's problems, too. Including ours.

There's no other investment that pays off nearly as well as one in education.

Is It Time To Change?

A letter from Brent Putnam N8UBD asking about combining the Novice and Tech licenses got me to thinking . . . always a bad sign. Now I know you are perfectly happy with the Novice, two kinds of Tech, the General, Advanced, and Extra Classes of license. And I know you really hate change. So what I'm going to discuss you're probably going to hate. Worse, I'm going to ask you to actually . . . gasp . . . think! Yes, I'm being sarcastic, thereby offending the half of you who actually do enjoy thinking, and at the same time offend-

ing the other half who find the whole concept of thinking alien.

I like to tackle problems by going back to basics and forgetting whatever Byzantine things have evolved so far. In the case of our amateur licenses let's first think about what the purpose is of having licenses. Do we need 'em?

I remember when I posed this question to the FCC about CB licenses. It had never occurred to them not to license CBers, so they were spending millions doing it. I asked them why. They didn't have any good answers other than they'd always licensed transmitters. And maybe the fact that there was a license would tend to make CBers obey the rules. Har-de-har. It took awhile for my reasoning to break through the bureaucratic minds, but eventually they gave up on issuing CB licenses. The sky did not fall. Saged a little maybe.

Okay, what purpose does a ham license serve in 1993? Well, let's start with the exam . . . what purpose does it serve? Perhaps we can start by asking what do we really need to know to operate? I'd go back one more step in the obvious questioning and ask what is the purpose of the Amateur Radio "Service" in 1993, except that the answer would just tend to embarrass us and might, if the concept ever penetrated the government, lead to some unpleasant consequences.

Let's pretend that we're still able to fulfill some of our original responsibilities. Let's pretend that we are still paying our way in exchange for billions of dollars in precious frequencies. It's been a generation since we invented or pioneered any new modes, so we can scratch that one. The military hasn't called on us in time of war for 50 years, so we can scratch that one. International friendships? Nope, scratch that one too. We have few friends. We're Ugly Americans on the air. Okay, we are still around in emergencies, so that's something. Of course our traffic nets are hardly beyond smoke-signal speeds when it comes to throughput in this day of 9600 baud.

The technical part of our exam is geared to the days when we built and serviced our own equipment. These days we haven't a clue as to what is inside, much less have the test equipment and experience to try and fix it. What real purpose does the technical exam play these days?

Old-timers will remember back to 1963 when the ARRL proposed what was amusingly called Incentive Licensing. This was a proposal that everyone have to retake a technical exam before they could continue to operate on phone on any bands between 160m and 10m. This scared the living hell out of everyone. Take the exam again? No way! Tens of thousands of hams put their ham gear up for sale for anything they could get for it. This killed the market for new equipment so totally that ham industry sales dropped by 85% in 1964. This, in turn, forced 85% of the ham dealers out of business, as well as virtually all of the manufacturers. Within a couple years we'd lost over 700 ham stores, plus Hallicrafters, Hammarlund, National Radio, Millen, EF Johnson, Barker & Williamson, Central Electronics, Gonset, Sidelband Engineers, Multi-Elimac, Harvey-Wells, Lakeshore Industries, Thordarsoon, Stancor, Eldico, and so on. Collins hung in there, but stopped all further product development, and

Continued on page 84

From The Hamshack

Ted Brattstrom NH6YK, Honolulu HI Wayne, in your eternal challenge to get hams off their rear ends and doing something new, I figured that I'd let you know what I've been up to in the two years since I received my license:

"Contacted" 106 DXCC countries on 10 meters (60 confirmed).

Had great conversations with a number of people, some of which I have even spoken to more than once!

Spent a lot of time playing with 10 meter SSB.

Had chats with U5MIR, U6MIR, and KB5SIW, using an HT and either a 5/8 whip on the car or a three-element hand-held beam. (Hawaii and Midway are great for this—there are few hams and not many of them are into satellites.)

Used the U5MIR-1 BBS to send messages to people and vice versa.

Set up and run TCP/IP on packet. Demonstrated amateur radio to two educational technology conferences.

Helped six of my students get their ham licenses (mixed success here—I left that school and few of them have used their privileges).

Operated as NH6YK/ZL on 2m and 70cm in New Zealand. They have a brilliant rule there that states: If you are a legal amateur and authorized at home on VHF and have your license with you, you may operate 2 meters and above for up to four weeks without filling out a form! Merely use your call and append portable ZL. Wouldn't it be great if we had that rule?

Operated NH6YK/KH4 when I spent seven weeks on Midway atoll last summer. Although I operated only 10 meters and 6 meters (a couple of CW contacts each on 15, 40, 80), I made over 800 contacts. Except on 6 meters, a contact usually lasted long enough to tell people a little about the island and what I was doing there. I was a volunteer for the Fish and Wildlife Service, playing with gooney birds.

Learned (and am learning) about 6 meters. From Hawaii it is ALL DX, and fascinating. I had a borrowed 6 meter radio and antenna on Midway and contacted five "countries." That was fascinating. On Midway I used 100 watts; here at home I use only 2 watts, either into a dipole (at home) or a borrowed four-element quad (at school). Amazingly, I've worked VK4, VK7, FK8, T30, V73, JR6, VR6 and KH6 with that power. One time I used my 10m half-square antenna as the 6m antenna. It worked! One nice thing about 6 is that people are very willing to help the neophyte.

Went on a Kalawao County DXpedition. A small troupe of us flew over and set up for the weekend. Since there are no active hams in the county, a former/current Hansen's disease colony, this was a relatively sought-after contact by some. I got to make my first AO-

13 contacts there. That was a lot of fun, and brought back the days I was station manager/operator for PEACESAT in American Samoa and using ATS-3.

I'm just starting to play with AO-21. I've now managed to pick up the digital recording, and I'm going to have to plug the TNC back into the computer and see if I can decode the packet! I'll try again tonight to make a voice contact on it with the 70cm up/2m down.

What's on the frontier for me: upgrade—get the code out of the way and gain access to those other frequencies; get more of my students licensed and operating; work on some radio astronomy; find some money or scrounge an ATV system; likewise, satellites.

I'll be operating in V31 and TI this summer, probably just 6m and 2m FM, unless I can convince the YL (also licensed) that a small 10m rig is reasonable amongst the cameras and scuba gear, and hopefully the E6B and charts so I can do a little flying also.

So, I try to keep up on the radio side of things. Oh, my real work is as a chemistry teacher at Pearl City High School.

Wayne, keep it up. If nothing more, you get people stirred up enough to do something. *Radio Fun* and *73* are great.

J. A. Fontana VE3MJF, Ottawa, Canada I'm a recently licensed ham (18 months) and have been alternately buying *73* and the "other" magazine off the rack, trying to make up my mind. This month I decided on and subscribed to *73*. I think, overall, that it has more that the "little guy" can relate to and it is not as esoteric as the other one.

I enjoy your editorials. I'd like to see a monthly "For the Sake of Argument" column in which you invite your readers to comment on something about the sport that troubles them, or needs fixin', or whatever. Something stimulating.

Good idea! . . . Wayne

Guy DeMarco N2LWL, San Diego CA I voraciously read your magazine from cover to cover. You seem to be able to print some of the most buildable (and usable) projects. Your department columns are top-notch.

But . . . (I'm sure you saw this coming!) I do have a gripe. I am an Avionics Technician in the Navy. I'm a bit put off by Wayne's moaning that us enlisted-type electronics specialists are "not what we used to be." I am finishing up my engineering degree in electronics and am an avid ham and teacher of electronics. While there are bad technicians who cannot read a schematic, please don't classify those of us who are proud of our accomplishments with the complacent service

members. There's always *one* bad presidential candidate. *One* does not prejudice all.

Yes, I'm a club officer, an Elmer, a teacher and a happy and challenged ham. Yes, I'm a college student and a defender of our constitution. Therefore, please do not toss out anecdotes about how awful the Navy technicians are. I'm sure didn't mean to stereotype us, but I'd be reassured if you could keep this in mind.

Tom Bowes KB8NDS, Richmond MI Wayne, I wanted to write to tell you how much I have been enjoying *73 Magazine* and the ham radio hobby I discovered about a year and a half ago. I look forward to picking up a copy of *73* each month and, of course, the first thing I turn to is your column. I find that I agree with you most of the time (pretty scary), and it is partly because of your input that I have continued to expand my knowledge by getting into computers and packet radio. The only thing I can't figure out is why your remarks seem to cause such a violent, knee-jerk reaction in some people. It is as if they were indignant that anyone should awaken them from the stupor of snoozing in front of the TV.

I caught your presentation at Dayton and found it thoroughly enlightening and thought-provoking. I agree with you wholeheartedly about our alleged emergency service role and its overall lack of efficiency. I participated in my first RACES exercise last fall and was immediately convinced that there had to be a better way. One month later I bought a TNC, a \$10 dumb terminal and a secondhand 2 meter rig and voilà, I became a packeteer. Now all I have to do is convince our local RACES group to really get serious about developing an effective packet network. You have mentioned the ridiculous nature of the CW traffic-handling nets. I'll add to that by mentioning the ridiculous nature of the phone-traffic-handling nets. All this "Would you please repeat, I didn't get the right count" and "Sorry, I couldn't copy you because somebody doubled" stuff has got to go. It's no wonder most amateurs aren't involved in emergency communications. The speed of most NTS and emergency phone nets reminds me of when I was a kid playing my 78 rpm records on the 33 speed. Things just go soooooo . . . slooooo. I couldn't take enough No-Doz to deal with the pace of most nets.

While at Dayton I spent some time lobbying the major radio manufacturers with my idea of how they could improve their products and help out the amateur radio operator's emergency service role. What I am proposing is that they incorporate into the design of every radio a separate packet port on the rear of the radio. This port would be configured with the same pin configuration for every radio manufacturer, and eventually for every TNC. The radio would also be programmable to allow disabling of the microphone and speaker audio during digital operation. It would also allow the packet port to be disabled

when on a phone frequency preset. This feature would help to eliminate the problem of those who forget to turn off their TNC when changing frequency and consequently end up transmitting packet tones on a phone frequency and consequently end up transmitting packet tones on a phone frequency. It would also allow one to work packet without having to find a way to eliminate the annoying "brap-brap" of the rig's speaker.

My reason for proposing a standardized port configuration is that I have heard of too many instances where an emergency packet station has been rendered inoperative because the radio failed. While there were other radios available for use, none could be used because of the lack of a proper interface cable. By having all rigs configured the same way we could increase our flexibility in an emergency situation. My proposed data port configuration would be the venerable 9- (or 15-) pin female D-sub connection. Think of it—the cables would be inexpensive (about three bucks), widely available, and by the virtue of the thumbscrews on the cable hood they couldn't pull out of the back of the rig as my DIN connector is so fond of doing. Now, I realize that all this practicality would likely cost our beloved radio manufacturers some revenue due to the lost sales of adapters and specialty connectors, but I am convinced that they could probably come up with some other scheme to get our hard-earned dollars.

In addition, all of these radios would be set up for 9600 baud operation right out of the box, without the additional hassle of modifications. I would also like dual-band rigs to come with the ability to run packet via the data port on one band, while being able to simultaneously accommodate phone operation on the other band via the microphone jack and internal speaker. Or . . . the dual-band rig would be able to run packet on both bands at the same time and would be interactive with the TNC, via one of the data connector's pins, to allow remote operation of a digital crossband mode while using only one TNC. There would also be a +13.8 volt terminal built into the connector in order to eliminate the need for a separate power supply for the TNC. Although it may sound like I have my head in the clouds with this radio design wish list, there is really no reason why all of these features could not be incorporated into a rig with the technology that is now available.

The reason that I am writing to you, Wayne, is to enlist your support for these design goals for our radio gear. It is my hope that by incorporating these improvements into our radios, more operators will be encouraged to get into digital modes. Hopefully, with some publicity, and amateur operator support, we will soon see a new generation of rigs which are truly plug-and-play with respect to the up-and-coming digital modes.

Great idea! . . . Wayne

Uh-Oh, Canada!

Earlier this year, a major snafu in our distribution system caused all Canadian subscription copies of *73 Amateur Radio Today* to be held up in a warehouse somewhere (presumably) close to the Arctic Circle. By the time we got a sled team together to retrieve the magazines, Canadian subscribers had missed a couple of issues. By now, all Canadian subscribers should have received all of the missing issues.

As a way of making amends to our ham radio brethren (and sisters) north of the border, all Canadian subscribers active on March 1, 1993, will have two free issues added to the term of their subscription. We know that this in no way makes up for the trauma of not receiving your regular dose of *73 Amateur Radio Today*, but we hope you'll forgive us anyway.

New Repeater Packet Rules Proposed

The FCC has taken a long-awaited step towards establishing new policy for ham stations involved in automatic message forwarding. The commission has adopted its Notice of Proposed Rulemaking—a measure which foreshadows new regulations which will hold repeater control operators harmless for any prohibited communications instantly retransmitted through the repeater.

Under the new rules, only the originators of instantly-retransmitted communications are to be held accountable for content violations flowing through a repeater. But when it comes to packet, the FCC wants to hold both the originating and first forwarding station licensees responsible for prohibited communications. The idea is that a packet message could be reviewed, but repeater traffic is instantaneous.

Under the rules currently in effect, each amateur station is fully responsible for assuring that the contents of every transmission from his or her station complies with the rules. Generally speaking, this was never a problem for hams until the advent of high-volume, high-speed digital message forwarding systems. *TNX W5YI Report, Vol. 15, April 15 1993.*

Details Released on 219-220 MHz Access

The FCC has fleshed out its Notice of Proposed Rulemaking to "... provide a secondary allocation for the Amateur Service in the 219 to 220 MHz band to be used for amateur auxiliary station (point-to-point) packet backbone and other amateur point-to-point fixed communications." In response to a petition filed by the ARRL, the commission is proposing to allocate, on a secondary basis, the 219-220 MHz band for inner city wideband

packet radio networks and other point-to-point fixed operations.

According to the commission, this will (a) relieve the congestion in the 222-225 MHz band, (b) encourage the development and implementation of a packet network that can be used for emergency and national defense communications, (c) facilitate connection of local packet nodes to form such a regional or nationwide network, and (d) provide spectrum for exploration of new technology. *TNX W5YI Report, Vol. 15, April 15 1993.*

ITU up to 176

Three new countries from the former U.S.S.R. have joined the International Telecommunication Union as members so far this year. They are Georgia, Slovakia, and Kazakhstan. The ITU now has 176 member nations. *TNX W5YI Report, Vol. 15, June 1 1993.*

Special Club Callsigns Approved

The FCC has amended its Amateur Service rules to provide for volunteer organizations to administer a system designed to provide special callsigns to club and military recreation stations. This action was authorized by the Telecommunications Authorization Act of 1992. Organizations selected for the new system will be known as "Club and Military Recreation Station Call Sign Administrators."

To qualify, the club must exist for the purpose of furthering the Amateur Service, must be comprised of at least one percent of all hams licensed by the FCC, and must be capable of serving as administrator in all places where the Amateur Service is regulated by the FCC.

Each administrator will be assigned a block of two-by-three-letter callsigns. Dates for accepting administrator applications have not yet been announced. *TNX Westlink Report, No. 650, May 27, 1993.*

Consolidating VE Programs

Novices will soon be folded into the same licensing examination process as everyone else, under an FCC measure adopted on May 3rd. Currently (at press time), there are two different examination programs in the Amateur Service. For years, Novices have been informally tested by two volunteers. The Technician through Amateur Extra Class candidates have been tested under the VEC system—using teams of three accredited Volunteer Examiners. The three are managed by a Volunteer Examiner Coordinator who acts as a liaison between the VEs and the FCC.

Apparently, the Commission likes the way that the VEC program is going, because the

rate of errors has plummeted and the system is saving taxpayers an estimated \$1 million each year. The Novice testing system has an estimated error rate of nearly 10 percent and data collection has also been a weak point. The commission also hopes to minimize fraud by consolidating the VE programs.

The new FCC rules take effect July 1, 1993, placing responsibility for the preparation and administration of the Novice Class operator license examinations under the VEC system. The commission also has decided to allow for recovery of out-of-pocket costs for coordinating and administering such examinations. *TNX W5YI Report, Vol. 15, June 1 1993.*

Senator Extols Amateur Service

A Joint Resolution (S.J.90) has been introduced in the United States Senate recognizing the achievements of radio amateurs. Senator Charles Robb of Virginia drafted the bill, which calls for a national policy supporting amateur radio.

The resolution urges adoption of rules and regulations that encourage the use of new technologies within the Amateur Service. It also requests that any regulations which are necessary at any level of government be crafted in ways that encourage ham radio as a public benefit. *TNX Westlink Report, No. 650, May 27, 1993.*

French Launch Orbiter

A new satellite has joined the amateur radio community. Sponsored by the French Radio Amateur Club de l'Espace (RACE), the ARSNE (UO-22) satellite was sent into orbit from an Ariane-4 rocket right on schedule on May 12 at 00:56 UTC. It was launched from the European Space Agency's spaceport in Kourou, French Guiana, on the northern coast of South America.

After all the minor bugs are worked out of the satellite, the ARSNE will be open to packet traffic from all radio amateurs worldwide. The orbiting digipeater is equipped with an uplink frequency of 435.100; downlink 2446.5 MHz. *TNX W5YI Report, Vol. 15, June 1, 1993.*

A Decade of Packet

An anthology of 73 packet radio articles from 1983 to 1993.

by Charles Warrington WA1RZW

It may seem hard to believe, but the new technology we call packet radio has been gaining popularity with hams for some 10 years now! Regular readers of 73 know this magazine has given the subject intensive coverage. Not only will you find Jeff Sloman N1EWO's monthly column, "Packet & Computers," but you'll also find a compendium of construc-

tion articles, product reviews, and a few surprises—ranging from backpack units to space shuttle communicators.

If you've waited 10 years to get into packet, perhaps this little treatise is just the boot your system needs. Here you will find a handy-dandy index of 73 packet articles, and a brief abstract of each. We have also in-

cluded separate listings of packet columns and packet product reviews. Now you can dig out whatever information you need for a painless packet primer. If, on the other hand, packet is already part of your ham radio repertoire, we hope you will find this to be a valuable resource which will help to enhance your knowledge and future enjoyment.

Chronological Listing of 73 Packet Articles

"Join the Packet-Radio Revolution. Get error-free, high-speed communications. Packet radio's chief architect, WA7GXD, explains what it is and how it works." (by Lyle Johnson, Sept. 1983, p.19.) "This article is written to give the reader a practical look at packet radio, including a practical description of the equipment needed to use this new communications mode. . . . While the reading should prove interesting, the application of packet radio in *your* hamshack is the primary goal."

"Join the Packet Radio Revolution, Part 2. Warm up your soldering irons. This part offers the nuts and bolts of building your own TNC." (by Lyle Johnson WA7GX, Oct. 1983, p.20.) The author describes the Tucson Amateur Packet Radio (TAPR) Terminal Node Controller (TNC), and gives enough detail for the homebrew artist to build one.

"Join the Packet Radio Revolution, Part 3. Don't mess up. Packet protocols and procedures are all-important, says WA7GXD, and he's been right so far." (by Lyle Johnson, Jan. 1984, p.36.) In the final installment of his three-part series, WA7GXD illustrates the formal rules governing packet information transfer and tips for practical application.

"GLB Update" (QRX, March 1985, p.7.) "Packeteers using GLB TNCs, in particular those using them as digipeaters, should contact GLB for an update of their software." This short item includes where to send PROMs for update.

"Packet Places" (QRX, May 1985, p.8.) This short item presents a list of frequencies where you can find packet activity at various locations around the country.

"TAPR Two-Tone" (QRX, Sept. 1985, p.7.) This short item offers a commercially-made cabinet for the TAPR TNC-1 from Heathkit.

"Packet Panic!" (QRX, Nov. 1985, p.8.) This short article outlines packet radio's rapid

growth and some recent software developments.

"Packet Reprieve" (QRX, May 1986, p.7.) Short news item explains that, for the present time, third-party traffic sent via packet radio is legal—per the FCC.

"TNC Fix" (QRX, May 1986, p.7.) Item contains a modification which can be performed on a TAPR TNC-2 or an AEA PK-80 to prevent interference.

"A Packet Primer. First you've got to know the lingo." (by Gwyn Reedy W1BL, Aug. 1986, p.28.) In this comprehensive article, the author discusses why packet is becoming so popular. He compares packet's advantages and disadvantages with those of its technological ancestors.

"How to Make Friends at 1200 Baud. W2JU's guide to AX.25 etiquette." (by Norm Sternberg, Aug. 1986, p.34.) "This article offers a few collected thoughts and suggestions about: bandwidth of transmitted signals, transmitter keying characteristics and time constants, TNC parameter values (especially timing), beacons, and channel courtesy and good manners."

"Precision Packet Tuning. Build the ultimate digital tuning indicator for packet or RTTY." (by John W. Langer WB2OSZ, Aug. 1986, p.40.) Includes the schematic, circuit board design, parts list, etc. for constructing this project.

"So You Want To Be A Sysop? It's not as easy as it looks." (by Jon Pearce W2MNF, Aug. 1986, p.50.) "This article describes some of the trials, tribulations, frustrations, and rewards of becoming a packet BBS sysop." The article is also useful reading for the user, and includes instructions for smooth system operation.

"Birds 'N' Bauds. Satellites are going digital in a big way—Five international experts combine to define our place in space." (by Harold Price NK6K, Tak Okamoto JA2PKI, Hanspeter Kuhlen DIYQ, Peter Guelzow B2OS, Donald Moe DJ0HC/KE6MN, Aug. 1986, p.58.) This article discusses the frontiers of ham satellite technology and provides hints on how to take advantage of these advancements.

"Connect Alarm! Let your TNC call you when it has something to say." (by Louis I. Hut-ton K7YZZ, Aug. 1986, p.66.) A quickie construction project which, when attached to your TNC, sounds an alarm whenever there is a connect to your packet system.

"Survival Training For Mountaintop Digipeaters. A ROM with a view." (by George Flammer WB6RAL, Aug. 1986, p.68.) "This article describes a network of mountaintop digital repeaters covering the state of California." It includes network goals, trials and tribulations, and a look at the future.

"Beyond Level Two. High-level networking comes to packet radio." (by Phil Karn KA9Q, Aug. 1986, p.74.) "This article is for the user who is ready to take the advanced packet course. It discusses issues at the center of the next round of technical development."

"And If That Wasn't Enough . . . NK6K takes questions from the audience." (by Harold Price, Aug. 1986, p.80.) Five pages of packet questions and answers.

"On The Shelf" (by Harold Price NK6K, Aug. 1986, p.86.) An amateur packet bibliography. A good source for further reading.

"Packet Lunacy" (QRX, Oct. 1986, p.7.) In this short news item, W3IWI has successfully bounced packets off the moon.

"G/ACK" (QRX, Feb. 1987, p.7.) Short news item features a breakthrough for packet radio in Great Britain.

"Packet RATS. WA3DNN's Resume-After-Transmit Scanner lets your IC-27A do double duty." (by David C. Wolovitz, May 1987, p.30.) This construction article allows you to upgrade your IC-27A by connecting this home-brew Resume-After-Transmit Scanner to your digipeater.

"The Digital Novice. K9EI covers the basics and terminology of ham's digital world—from Samuel Morse's basement to packet proficiency." (by Jim Grubbs, June 1987, p.28.) The author presents options for the beginner who has

not yet experienced any of ham's digital communication modes.

"Big Time Packet. KITE can control a packet station from his desk or anywhere in the world—with a little help from his computer." (by Bradshaw B. Lupton, Jr., July 87, p.44.) The author describes how his passion for packet has made his workday lunch hour (and his correspondence) move along quickly.

"The Year 2000—Packet Radio Then and Now. The author predicts packet radio of the future—using today's technology." (by Bill Ashby K2TKN, Aug. 1987, p.24.) The author gazes into his crystal ball and attempts to describe the state of the art in the next millennium.

"AI on Packet?" (by William McMullan KE5L, Aug. 1987, p.29.) The author presents his "TRON" computer program, which will run your packet station automatically but does not actually use AI (artificial intelligence).

"U.S. Packet Digipeaters/PBSs" (by Don Bennett K4NGC, Aug. 1987, p.33.) A list of packet digipeaters and packet bulletin boards reported to be on packet radio in the United States.

"IC-2AT Packet Interface. Use WB5WSV's external PTT circuit to get on packet with an IC-2AT and an MFJ-1270." (by Wayne Eleazer, Aug. 1987, p.49.) This article shows you how to build a circuit which will allow the IC-2A to key up when connected to an MFJ-1270 TNC.

"On the Road and On the Air. Tales of a high-tech nomad." (by Steven K. Roberts KA8OVA, Feb. 1988, p.11.) The author developed a high-tech bicycle equipped with packet radio, among other things. He also discusses life on the road with his bike.

"Emergency 'Pocket' Packet. Instant packet in your jacket." (by David McLanahan WA1FHB, Apr. 1988, p.25.) A complete portable emergency packet station utilizing the ICOM O2-T, the GLB K1-L TNC, and the NEC 8201A laptop.

"Bicycle-Mobile Packeteering. It's time to pull packet radio out of its infancy!" (by Steven K. Roberts N4RVE, Apr. 1988, p.41.) The author picks up where he left off in his February article.

"The Care and Feeding of a PBBS. Timely tips for packet bulletin board users (Part 1)." (by David McLanahan WA1FHB, June 1988, p.23.) "One of the perks of working packet is being able to access one or more of the Packet Bulletin Board Systems springing up all over the country." The author teaches you how to take advantage of these PBBSs.

"Care and Feeding of a PBBS. Timely tips for packet bulletin board users (Part 2)." (by David McLanahan WA1FHB, July 1988, p.60.) The author continues where he left off in Part 1 with some final tips for packet BBS users.

"Digicom>64. A software-based packet radio system for the Commodore 64." (by Barry

N. Kutner, M.D. W2UP, Aug. 1988, p.22.) A cheap 'n' easy packet radio system, including circuit descriptions and schematics.

"Packets Full of Pixels. Packet Scan Amateur Television." (by Robert G. Pratt WD8AQX, Oct. 1988, p.10.) The author has found a way to combine amateur radio, computers, and video into "... a fun-filled super hobby that results in very slow-scan television images sent across town or around the world via packet radio."

"Ham Call Directory on Packet." (QRX, Nov. 1988, p.9.) A short news item. A Virginia ham (no pun intended) has compiled a CD ROM database of US amateurs which is accessible by packet radio.

"Scotland" (QRX, Dec. 1988, p.9.) Tiny news item. "Packet digipeating has come to Scotland."

"Packet Tuning Indicator. Dead-on HF packet tuning for \$15." (by Ronald B. Koester W2EKY, Dec. 1988, p.24.) This easy and inexpensive construction project includes the schematic, circuit board design, and parts list.

"TCM 3105 Modem for the Digicom>64. A mini-modem for 1200 baud packet." (by Craig Rader N4PLK, John Krohn KJ4GP, Sam Baine W4KUM, and Mike Zincola WD4PVS, Feb. 1989, p.42.) This project is a modem for the Digicom>64 TNC Emulator program that works exclusively on 10 meters, VHF, and UHF at 1200 baud. Circuit board design, parts placement diagram, and schematic are provided for this small and inexpensive home-brew.

"Getting High on Packet. Excellent advice for getting on HF packet." (by Brian Lloyd WB6RQN, Feb. 1989, p.50.) This "how to" article gets you started on HF packet including theory and practical operating suggestions.

"The Net/ROM-NordLink Question. A case of software piracy?" (by Neil Shapiro WB2KQI, June 1989, p.34.) A discussion of a legal battle over software rights which an American firm claims were violated by a German firm. The software in question was designed to enhance packet radio data transfer.

"Packet Racket Lip Zipper. Automatically turns off your rig's speaker during packet operation." (by Michael J. Geier KB1UM, Oct. 1989, p.13.) "The Lip Zipper switches the audio output of your rig from an external (or internal) speaker to the audio input of your TNC. In addition, you can use it to switch the rig's mike input between the mike and the TNC." Schematic and parts list are included.

"Setting Up a Packet Radio Station. An excellent guide for beginners and veterans alike." (by Brian Lloyd WB6RQN, Oct. 1989, p.14.) This is a step-by-step guide for the packet beginner which discusses equipment selection and how to configure the system.

"My SX-64 Runs Digicom! Low-cost packet solution for your portable C-64." (by Ted Drude KA9ELV, Oct. 1989, p.24.) "If you couldn't figure out how to get Digicom running

on your SX-64 portable, you can get the complete story here, including how to modify Digicom modems to work with the SX-64, and how to make the proper internal connections."

"Digital Dreams. We have not yet begun to packet!" (by Bdale Garbee N3EUA, Oct. 1989, p.28.) This article describes ways in which you can "turbo-charge" your packet station. The author discusses a variety of frequency options, networks, and software advancements to help the packeteer reach his or her potential.

"Let the TNC Work While Your PC Sleeps. Give your older TNC personal mailbox capability—with no hardware changes!" (by David Bartholomew WB6WKB, Oct. 1989, p.30.) This brief article outlines a procedure by which you can "turn your packet answering machine on."

"Put Your IC-22S on Packet. Dust it off and dedicate it to 2m packet!" (by Michael S. Dooley KE4PC, Oct. 1989, p.31.) "Are you tired of tying up your synthesized radio on packet? If you have access to an ICOM IC-22S, a fast and easy fix will get it on this fascinating mode."

"KAM Box. Packet and WEFAX for the lazy." (by Joe Davidson N4AQQ, Oct. 1989, p.32.) The author tells you how to modify the Kantronics UTU to allow you to take advantage of packet and weather fax modes. "These alterations have made a very nice operating interface just a little more friendly."

"One-Chip RS-232 for the C-64. Easy and inexpensive RS-232/TTL level interface." (by Mike Kabala KBØCDQ, Oct. 1989, p.34.) The author explains how you can build an interface to convert all the Commodore's signals from TL levels to levels that agree with the EIA standard. PC layout and parts list are included.

"Packet Radio in Japan. Bits of information on packet in the land of the Rising Sun." (by David Cowhig WA1LBP, Oct. 1989, p.38.) A news roundup of packet radio in a country the size of California with 1.6 million hams.

"Standardizing the Radio/TNC Interface. Patch any rig to any TNC or data controller in just a few moments!" (by Brian Lloyd WB6RQN, Oct. 1989, p.40.) The author describes the perfect interface (project) for that packet-rat ham who has collected five different radios and five different TNCs.

"Packet Radio and High-Tech Nomadics. A sneak preview of the Winnebiko 3." (by Steven K. Roberts N4RVE, Oct. 1989, p.48.) The author is the inventor of computerized, ham-radio-equipped bicycles which he has pedaled across the United States. This article examines his third generation bike, which is packet equipped.

"Improve your TNC's DCD circuit. Make your DCD faster and more discriminating." (by Eric Gustafson N7CL, Oct. 1989, p.50.) "The DCD circuitry for nearly all currently available TNCs are deficient for use on a radio channel.

Some are better than others, but most can be dramatically improved." A schematic is included for this project.

"TexNet Packet-Switching Network. An overview of a highly successful and efficient packet radio network." (by Greg Jones WD5IVD, Oct. 1989, p.54.) TexNet is "an inexpensive, multi resource, four port, high-speed 'backbone,' datagram-based amateur packet switching system." The author presents an overview of a very fast 9600 baud amateur network.

"Amateur Packet Networking. Going beyond just AX.25 . . ." (by Brian Lloyd WB6RQN, Oct. 1989, p.60.) "This article covers some networking concepts, explains where the original popular ham packet protocol, AX.25, falters, and compares and contrasts the more popular networking protocols."

"TCP/IP for the Macintosh. Now this powerful PC runs one of packet radio's hottest networking systems!" (by Doug Thom N6OYU and Dewayne Hendricks WA8DZP, Oct. 1989, p.68.) Transport Control Protocol/Internet Protocol can provide hams with many capabilities never before available in packet communication. The article includes an address where you can purchase the program on disk for \$5.

"HF Packet Tuning Aid. Spot-on tuning every time!" (by John Reed W6IOJ, Oct. 1989, p. 80.) Build this easy to use packet signal synthesizer. The schematic and parts list are included.

"The Quickchanger. This makes mixed-mode/band operation a breeze." (by Howard E. Cann KA3MRX, Oct. 1989, p.84.) This easy home-brew is "an interface box that lets you switch a single mike, a TNC, a phone patch, and two speakers, all to either HF, VHF, or off."

"The Great San Francisco Quake '89. Hams fulfill the purpose of the amateur radio service." (by Bill Pasternak WA6ITF, Feb. 1990, p.18.) Digipeating Packeteers prevailed in the big earthquake's emergency communications.

"Grant for HF Packet Research" (QRX, Apr. 1990, p.7.) Tiny news item. "A team will investigate the benefits of diversity reception for HF packet radio . . ."

"SAREX-90. Ham-in-space shuttle missions." (by Tom Clark W3IWI, Ron Parise WA4SIR, and Bill Tynan W3XO, May 1990, p.9.) This comprehensive article on hearing and working the astronauts includes a section on packet.

"SateLife Packet." (QRX, June 1990, p.7.) Experts in Boston and Moscow are teaming up to save lives by bringing lightning-fast medical data to third world doctors via packet.

"TNC Connect Alarm. Did anyone call when I was out?" (by Mark Schmidt DA1AU/WB9EGA, June 1990, p.14.) This easy home-brew is like an answering machine for your packet radio station.

"PK-232 Connect Memory. Lets you know what you missed. (by William Bleher W8GQL, July 1990, p.44.) This simple construction pro-

ject lets you know if a connection occurred to your packet station when you were away.

"SAREX Packet Hints." (QRX, Nov. 1990, p.7.) Advice for successful shuttle communications including using the proper call sign.

"Portable Backpack Packet Station: Behold the Back Packet! Go take a hike with packet radio." (by John Trent Adams NW6H, Dec. 1990, p. 9.) You can " . . . provide reliable communications at a moment's notice from any weird location . . ." with this innovative project. "The BackPacket consists of a PacComm Micropower-2 TNC, an Epson PX-8 laptop, a Yaesu FT-203 HT, a 7 amp-hour sealed lead-acid battery all encased in a sturdy Ensolute laminate in a Jansport daypack."

"Upgrade your HD-4040. KISS your Heath D-4040 and keep X.25 too!" (by Mark Dieter N2BLI, Dec. 1990, p.19.) "Very few parts are required to install this upgrade in your TNC: the TAPR KISS TNC 1 EPROM, a good quality DPDT switch, and a few strands of small-gauge wire."

"W1AW Packet BBS." (QRX, Jan. 1990, p.7.) "The ARRL has reinstated its packet radio BBS, W1AW-4, after more than a year off the air."

"Packet with the Microsats. The secrets of success." (by David Medley KI6QE, March 1991, p.9.) A seasoned ham (sorry) shares his favorite tidbits for getting the most out of orbiting packet.

"The End of Packet." (QRX, April 1991, p.7.) A chill was sent through the packet radio community when eight amateurs were fined \$300 each in connection with a political message. This appears to be the first time the FCC has penalized intermediate packet station operators for a message they did not originate.

"New Rules Sought" (QRX, May 1991, p.7.) "The FCC has accepted a petition requesting that primary responsibility for the content of all automatically retransmitted signals be placed on the originating station."

"Packet Challenge" (QRX, July 1991, p.7.) This is another update on the FCC fines for automatic packet message handlers.

"Poor Man's Packet. A complete software TNC for PC compatibles!" (by F. Kevin Feeney W2EMS and Andy Payne N8KEI, Aug. 1991, p.8.) This home-brew uses your PC to do the work of the TNC. The software is on disk instead of ROM. "Using this design you can build a simple, inexpensive packet communications system." It's a good way to get your feet wet in packet.

"The Lappack. Extended portable power for your laptop computer." (by Brian Kassel W5VBO, March 1992, p.52.) This construction project provides the 9.2 VDC required by some laptops by converting power from a 12VDC source.

"Packet on the Mac. Connect with the world without a TNC." (by Dexter Francis KD6CMT, Oct. 1992, p.8.) This article has all the information you need to build a 'PacketMac

Modem,' which will eliminate the need for an external TNC. A PC board is available.

"Packet Radio and Emergency Communications. Public safety enters the digital world." (By Richard Ferguson KAØDXM, Oct. 1992, p.42.) A comprehensive look at emergency packet is presented, including what you'll need to know to start a successful ham radio emergency group.

"ARRL Kills Automatic HF Packet Forwarding." (QRX, Nov. 1992, p.7.) In this short news item, the league has decided to accept the Digital Committee's recommendation that unattended HF packet forwarding should not be allowed.

"IARU Region 2 Meeting Formally Recognizes HF Packet." (QRX, Dec. 1992, p.6.) "The International Amateur Radio Union Region 2 Conference was held . . . and the decisions will definitely have an impact on the future of high-frequency fully-automatic packet radio forwarding worldwide."

"Packet Radio Equipment Needed for Poland Center." (QRX, March 1993, p.8.) The American Council for Polish Culture is seeking new or used packet equipment to enhance training opportunities.

"Digital Satellite Gateway Nodes. How to get on OSCAR 22 with an HT." (by John A. Hansen WAØPTV, March 1993, p.19.) "The satellite gateway node system is a fairly new development in packet radio satellites. It permits region-wide access by hams with anything from very modest equipment to the latest in digital satellite technology."

"Portable Packet Digipeater for Emergency Service." (by John Neeley K6YDW, June 1993, p.16.) Build this highly portable, battery powered digipeater. Parts list, schematics, and PC board design are all included.

Chronological Listing of 73 Packet Columns

"NK6K>Packet" (by Harold Price, May 1986, p.86.) In this first packet column, the author introduces you to some **packet radio definitions** and reviews the history of packet. He also explains why packet is virtually error-free.

"NK6K>Packet" (by Harold Price, June 1986, p.76.) The author continues his discussion of **packet basics** including a discussion of the costs involved in getting started.

"NK6K>Packet" (by Harold Price, July 1986, p.88.) A discussion of the **new packet products** offered at Dayton this year.

"NK6K>Packet" (by Harold Price, Sept. 1986, p. 88.) **Packet in other lands** is discussed, including Japan, South Africa, and the U.K.

"NK6K>Packet" (by Harold Price, Oct. 1986, p. 60.) The author discusses **baud rate** and how it is related to transceiver delay time.

"NK6K>Packet" (by Harold Price, Nov. 1986, p.74.) The author addresses a variety of

subjects including **moon bounce** on 432 MHz and third-party traffic in relation to packet operation.

"NK6K>Packet" (by Harold Price, Dec. 1986, p.66.) The first large-scale **packet radio survey** questionnaire is presented.

"NK6K>Packet" (by Harold Price, Jan. 1987, p.70.) The author discusses **high-speed modems**, HF forwarding networks, and restricted BBSs.

"NK6K>Packet" (by Harold Price, Feb. 1987, p.66.) The author discusses what should be included in a **packet message header**.

"NK6K>Packet" (by Harold Price, March 1987, p.82.) Results from the **packet poll** of December 1986 are presented.

"NK6K>Packet" (by Harold Price, Apr. 1987, p.76.) The author **answers questions** from readers. Topics include the recent survey and auto-forwarding.

"NK6K>Packet" (by Harold Price, May 1987, p.54.) The author reviews his **first year** writing a packet column.

"NK6K>Packet" (by Harold Price, June 1987, p.58.) The author delves into **coded packet transmissions**.

"NK6K>Packet" (by Harold Price, July 1987, p.56.) The author discusses the **AEA packet line**, OSCAR 12, and the FO-12 BBS.

"NK6K>Packet" (by Harold Price, Aug. 1987, p.50.) The author discusses the virtue of a **proposed FCC STA** (special temporary authorization) to allow HF stations to run unattended.

"NK6K>Packet" (by Harold Price, Sept. 1987, p.68.) The author continues his discussion of the **HF STA**.

"NK6K>Packet" (by Harold Price, Oct. 1987, p.54.) The author revisits the August 1987 packet issue and discusses using **laptops for packet**.

"Packet Talk—Latest in Digital Hamming" (by Brian Lloyd WB6RQN, Dec. 1987, p.59.) In his first packet column, the author discusses **transceiver enhancements** to better facilitate error-free packet communications.

"Packet Talk—Latest in Digital Hamming" (by Brian Lloyd WB6RQN, Jan. 1988, p.80.) The author discusses **protocols** and layer definitions.

"Packet Talk—Latest in Digital Hamming" (by Brian Lloyd WB6RQN, Feb. 1988, p.76.) The author looks at **narrow bandwidth FM** radios in common use on packet radio.

"Packet Talk—Latest in Digital Hamming" (by Brian Lloyd WB6RQN, Mar. 1988, p.76.) The author discusses **equalization and modems**.

"ATV" (by Mike Stone WB0QCD, Apr. 1988, p.58.) The author discusses **interfacing packet radio with amateur television**.

"Packet Talk—Latest in Digital Hamming" (by Brian Lloyd WB6RQN, Apr. 1988, p.67.) The author shows how packet radio can be used in an **emergency**.

"Packet Talk—Latest in Digital Hamming" (by Brian Lloyd WB6RQN, June 1988, p.60.) This column is devoted to building a **duplex digipeater for 2 meters** that requires little hardware and no software.

"QRP" (by Mike Bryce WB8VGE, June 88, p.67.) A short blurb describes **low power packet** operation.

"RTTY Loop—Amateur Radio Teletype" (by Marc I. Leavey, M.D., WA3AJR, August 1988, p.63.) Discussion of an **AEA PC Pakratt** program which can handle packet, Baudot, FAX, Morse, and AMTOR.

"Circuits—Great ideas from our readers." "Portable Packet" (by Dick Peters WA1PWF, Feb. 1989, p.76.) A very simple circuit which allows you to use your TNC with an ICOM HT.

"DX—Hams Around the Word" (by Chod Harris VP2ML, Feb. 1989, p.79.) **Packet DX Spotting Networks**, packet conference bulletin board, and packet cluster are discussed.

"73 International" "Packet Radio in South Africa" (by Peter Strauss ZS6ET, Apr. 1989, p.104.) A roundup of packet ham radio activities in the Republic of South Africa.

"Letters From the Hamshack." "Packet Racket" (Letter by John Shelley WA1IAO/response by Brian Hastings NS1B, May 1989, p.92.) Mr. Shelley calls packet an "electronic plague" while Mr. Hastings responds that clinging to the past could kill ham radio.

"Circuits—Great ideas from our readers." "Packet/Voice Switch Box." (by Robert L. Dingle KA4LAU, Aug. 1989, p.58.) A simple circuit you can build to avoid having to disconnect the input to the TNC and reconnecting the microphone in order to switch from packet to voice.

"Ask Kaboom—The Tech Answer Man" (by Michael Jay Geier KB1UM, Sept. 1989, p.61.) The author answers reader inquiry about a flickering DCD light when there is no signal on his **MFJ 1270 TNC**.

"Welcome, Newcomers!" (by Brian P. Lloyd WB6RQN, Oct. 1989, p.6.) A handy one page introduction to **packet terms and definitions**.

"Packet Talk—Latest in Digital Hamming" (by Brian Lloyd WB6RQN, Nov. 1989, p.50.) The author, returning from a one-year hiatus, discusses **packet bulletin boards and protocols**.

"Packet Talk—Latest in Digital Hamming" (by Brian Lloyd WB6RQN, Dec. 1989, p.46.) Topics this month include **courtesy using packet** on the ham bands and making AX.25 more efficient.

"Circuits—Great ideas from our readers." "3-Position, Multi-Mode Switch Box." (by David K. Pelaez, Dec. 1989, p.70.) Build an easy switch-box for RTTY, packet, FAX, and SSTV.

"Ask Kaboom—The Tech Answer Man" (by Michael Jay Geier KB1UM, Dec. 1989, p.72.) Fix a common cause of **QRM** on 2 meter mobile packet radio.

"Letters From the Hamshack." "Closer Look at ROSE" (A letter by Thomas A Moulton W2VY and response by Linda Reneau KA1UKM, Dec. 1989, p.76.) A reader responds to comments about the ROSE networking solution in a recent packet issue of 73.

"Packet Talk—Latest in Digital Hamming" (by Brian Lloyd WB6RQN, Jan. 1990, p.58.) Topics this month include two packet conferences, new products, and the **ARPANET/Internet**.

"Packet Talk—Latest in Digital Hamming" (by Brian Lloyd WB6RQN, Feb. 1990, p.58.) The author discusses ways in which **packet can be improved**, including better frequency coordination and more channels.

"Packet Talk—Latest in Digital Hamming" (by Brian Lloyd WB6RQN, March 1990, p.56.) The author talks about doing **800 Hz shift with the PK-232** and about a California grocery store which caters to computer hackers.

"Packet Talk—Latest in Digital Hamming" (by Brian Lloyd WB6RQN, Apr. 1990, p.54.) The author touches on the **universal interface**, PTT level converter, and the stagnation of packet radio.

"Packet Talk—Latest in Digital Hamming" (by Brian Lloyd WB6RQN, May 1990, p.58.) The author discusses **smart packet software** and especially SAREX features.

"Packet Talk—Latest in Digital Hamming" (by Brian Lloyd WB6RQN, June 1990, p.48.) The author discusses **10 meter packet** including upper and lower sideband operation.

"Hamsats—Amateur radio via satellite." (by Andy MacAllister WA5ZIB, June 1990, p.51.) **Modems for digital hamsat operation** are discussed.

"Packet Talk—Latest in Digital Hamming" (by Brian Lloyd WB6RQN, July 1990, p.64.) The author answers mail and discusses the **"TAPR packetRADIO."**

"Packet Talk—Latest in Digital Hamming" (by Brian Lloyd WB6RQN, Aug. 1990, p.76.) Includes more on **800 MHz shift** and more on **10 meter packet** discussion from a previous column.

"Homing In—Radio direction finding." (By Joe Moell P.E. KØOV, Oct. 1990, p.52.) The author discusses **triangulation** by packet.

"Hamsats—Amateur radio via satellite." (by Andy MacAllister WA5ZIB, Dec. 1990, p.81.) A discussion on **packet via satellites** is presented, including **picture packets** from space.

"Hamsats—Amateur radio via satellite." (by Andy MacAllister WA5ZIB, Apr. 1991, p.70.) How to copy the **Soviet Mir Space Station** on FM packet.

Continued on page 18

"RTTY Loop—Amateur Radio Teletype" (by Marc I. Leavey, M.D. WA3AJR, Aug. 1991, p.69.) "**Packet or RTTY—Which is better?**" The author compares and contrasts two of amateur radio's popular digital modes.

"Hamsats—Amateur radio via satellite." (by Andy MacAllister WA5ZIB, Dec. 1991, p.62.) The author talks about **9600-bit-per-second packet** operation via low earth satellites.

"RTTY Loop—Amateur Radio Teletype" (by Marc I. Leavey, M.D. WA3AJR, Feb. 1992, p.62.) The author walks a packet newcomer through his **anxiety** over the new digital mode.

"Packet & Computers." (by Jeff Sloman N1EWO, Aug. 1992, p.62.) In the first installment of his new column, the author reviews a number of helpful suggestions for **network users and sysops**. Topics include PBBS directory services and the WB7TPY Packet/Internet Gateway.

"Packet & Computers." (by Jeff Sloman N1EWO, Sept. 92, p.78.) Subjects include **tuning up** your packet station, networks, repeaters and portable packet.

"RTTY Loop—Amateur Radio Teletype" (by Marc I. Leavey, M.D., WA3AJR, Oct. 1992, p.54.) The author explains to an RTTY user what he needs to know to take that **big leap into packet**.

"Packet & Computers." (by Jeff Sloman N1EWO, Oct. 1992, p.64.) Subjects this month deal with **portable packet** operation: batteries, TNCs, and carrying cases.

"Packet & Computers." (by Jeff Sloman N1EWO, Nov. 1992, p.62.) This month's column is devoted entirely to a **digital radio glossary**.

"Packet & Computers." (by Jeff Sloman N1EWO, Dec. 1992, p.74.) Includes good news about the Internet and highlights of the **N0ARY BBS**.

"Packet & Computers." (by Jeff Sloman N1EWO, Jan. 1993, p.72.) A discussion of **digital signal processing and digital filters** is presented.

"Packet & Computers." (by Jeff Sloman N1EWO, Feb. 1993, p.66.) This month's column focuses on **TexNet**.

"Packet & Computers." (by Jeff Sloman N1EWO, March 1993, p.48.) The main topic this month is understanding **asynchronous communications**.

"Packet & Computers." (by Jeff Sloman N1EWO, Apr. 1993, p.40.) In this first installment of a series, the author tells you how to quiet down the **RFI** in your hamshack.

"Packet & Computers." (by Jeff Sloman N1EWO, May 1993, p.40.) The author presents the second half of his discussion on **asynchronous communications**. (See March 1993.)

"Packet & Computers." (by Jeff Sloman N1EWO, June 1993, p.50.) This month's column looks at how packet operators (and hams in general) need to improve their **behavior** on the airwaves.

"Packet & Computers." (by Jeff Sloman N1EWO, July 1993, p.58.) This month, the author covers **hierarchical addressing**, the system by which packet traffic is routed.

Chronological Listing of 73 Packet Product Reviews

"Seeing Packet Radio With Different Eyes. The **Versabraille 2** system allows blind hams to get connected." (by Jeffrey Bishop 7FDS, Aug. 1986, p.48.) The author reviews Telesensory Systems Inc.'s word processor and communicator for the blind. It can be used with nearly any TNC to facilitate sightless packet operation.

"**MFJ-1270 TAPR-2 Packet TNC**" (by Marc Stern N1BLH, June 1986, p. 24.) The author reviews "... packet (for) the common man ... a TAPR NC-2 clone that's every bit as good, if not better, than the original."

"**73's Packet Buying Guide**" (Aug. 1986, p.88.) Table lists company, product, features, and price.

"**AEA PK-232 PAKRATT**" (by Perry Donham KW1O, Dec. 1986, p.22.) Advanced Electronic Applications put all of ham radio's digital modes into one station controller. The unit includes Morse, Baudot RTTY, ASCII, AMTOR, and packet.

"**The Heath HK-21 TNC**. Hand-Held TNC!" (by Tom Gilchrist N7KHU, March 1989, p.38.) "Heath calls the HK-21 a 'Pocket Packet' for a very good reason. It's a compact, self-contained TNC with a built-in personal packet bulletin board system (PBBS)."

"**DRSI PC*Packet Adapter**. Revolutionizes the PC/transceiver interface." (by Brian Lloyd WB6RQN, Oct. 1989, p.20.) "This board plugs in to your IBM or compatible and turns it into a complete packet radio communications system."

"**GRAPES 56 Kb Modem**. We've come a long way from 1200 baud packet." (by Philip R. Karn, Jr. KA9Q, Oct. 1989, p.42.) "How would you like to be able to send the equivalent of a standard 5.25" IBM PC floppy disk (360 Kbytes) by packet radio in less than two minutes? How about transmitting telephone-quality digital voice over the air?" The author reviews a fast modem distributed by the Georgia Radio Packet Enthusiasts Society.

"**PacComm's NB-96 High Speed Modem**. Dramatically increase packet data rates without buying a new packet system." (by Thomas A. Moulton W2VY and Robert A. Buas K6KGS, Nov. 1989, p.30.) A review of a 9600-baud modem that enhances most packet radio systems with no need to change rigs.

"**Pkt-GOLD Multimode**. Your software window into the world of digital communications!" (by Marc Stern WA1R, Aug. 1991, p.20.) "Pkt-GOLD Multimode is a program that turned out to be one of the best implementations of multimode controller software I have seen."

"**The TAPR METCON-1 Kit**. Add telemetry and control to your packet station." (by Bill Brown WB8ELK, Aug. 1991, p.34.) "How would you like to have the ability to read sensors or control circuitry from a remote location via packet radio?" With this kit, you can do it.

"**The Kantronics KTU Telemetry Unit with Weathernode EPROM**. Remote weather observations via packet!" (by Dick Goodman WA3USG, Aug. 1991, p.46.) "The flexibility in the way weather data may be captured and presented should meet the requirements of the most demanding amateur and professional meteorologists."

"**The BayCom Packet System**. Run packet without a TNC." (by Dick Goodman WA3USG, Dec. 1991, p.20.) This system is actually composed of two parts: "... a shareware program called 'BayCom,' and a simple modem." The reviewer calls it superb.

"**The Kantronics KPC-3**. Full-featured packet in a compact package." (by Mark T. Schmidt WB9EGA, Oct. 1992, p.30.) This tiny packet communicator offers a long list of features, including WEFAX and KA-Node.

"**The Tigertronics BP-1 Packet Modem**. Just add one computer for instant packet. (by Bill Brown WB8ELK, Dec. 1992, p.52.) "How would you like to get on packet for less than \$50? If you have an IBM compatible computer laying around, you only need to add the BP-1 Packet Modem and run a software packet program."

"**The AEA DSP-2232**." (by Jeffrey Sloman N1EWO, March 1993, p.17.) This product "... is a great example of how DSP (digital signal processing) can bring intelligence and flexibility to a product traditionally hardwired for a job."

Special Packet Issues

On three previous occasions, we have devoted an entire issue of 73 to packet. These are "must read" issues. They were published in August 1986, August 1987, and October 1989. **73**

Back issues are available while they last for \$4.00 each ppd. Reprints are available for \$3.00 per article. Send orders to 73 Amateur Radio Today, Reprints, 70 Route 202N, Peterborough, NH 03458.

LED BACKLIGHT

1.57" X 1.08" X LED lighted backlight. Frequently used behind LCD displays to enhance visibility of characters. Four green LEDs, one in each corner, light the device. 0.12" thick clear plastic with white reflective backing. CAT # LED-BL 2 for \$1.00

6VDC, 4PDT KH STYLE RELAY

SPECIAL PURCHASE!!

Omron # MYQ4-02-VH-6VDC
6 Vdc, 37.5 ohm coil, PC pins.
4PDT, 5 amp contacts.
1.07" X 0.82" X 1.41" high.
CAT # 4PRLY-6PC
\$2.50 each
10 for \$20.00

REDUCED PRICE! 4 (USED) AA RECHARGEABLE BATTERIES

Battery pack with 4 AA nickel-cad batteries in series to make a 4.8 volt pack. Batteries have solder tabs and can be separated and reconfigured. CAT# NCB-41AAU SPECIAL 1 \$2.00 per pack

12 VDC LATCHING RELAY

Midtex # 327-21B200
12 Vdc, 400 ohm dual coil latching relay.
DPDT, 2 amp contacts. Fits 16 pin DIP socket. 0.8" X 0.4" X 0.33". UL listed.
CAT# LRLY-125 \$2.00 each

VIDEO/RF MODULATOR

Originally made for use with the Commodore computer, these good quality video modulators were probably designed for 9 Vdc use, but they operate well on 6-12 Vdc. They accept color video and audio, and a selector switch is provided for output to channel 2 or 3. Easy to hook-up. Requires a 6-12 Vdc power supply or wall transformer and a connector to interface with your audio/video source. RCA jack output. Hook-up instructions included. 3" X 1.47" X 0.75".

CAT# AVMOD-3 \$5.00 each

DC-DC CONVERTER

Satellite Technology Services, Inc. # AV 011

Input:
13.75 Vdc to 27.5 Vdc
Output:
13.75 Vdc @ 1.3 amps
Plugs into cigar lighter receptacle in car or airplane. Converts, filters and regulates voltage for use with 12-14 Vdc appliances. Fused cigar lighter plug on heavy duty 3 ft cable. 4 1/2 ft cord on output side terminates with a small DC co-ax power plug that, in most cases, will need to be cut-off and replaced with another type of plug. Ideal for powering portable TVs, communications equipment etc.
CAT# AV-011 \$5.00 each

FM Packet Deviation Meter

Put your packet station on the money for 20 bucks.

by Steven R. Sampson N5OWK

There are a lot of "plug-and-play" amateurs today, and many are working FM packet. While many traditional amateurs can draw a Bessel function chart with their eyes closed, this new breed of ham is a lot less technical. Many have a hard time digesting the concepts of bandwidth and frequency drift, never mind deviation. This article will help. It shows how to build a useful instrument, explains exactly why it is needed, and challenges the less-than-technical ham to expand his or her electronic expertise.

Like most newcomers to VHF packet radio, I set my system up by connecting all the cables and getting on the air. It wasn't too long before I checked my audio levels. Unlike voice, there aren't a lot of people who complain if your packet audio is too hot or too weak. Actually, I don't think anyone locally listens to the packet tones because I was hotter than a two dollar pistol. First I set my receive audio level, and this was simply an increase in volume until the TNC Data Carrier Detect (DCD) light illuminated, followed by a squelch adjustment (some TNCs can operate without squelch, and this is the better way to go). You can make a pretty good judgement about setting the transmitter audio level by listening with another radio, but the correct method is to use a deviation meter. You won't find inexpensive deviation meters at any radio store, so you're going to have to build one. This article presents a deviation meter based on William Crowl N6MWS's design from the January 1990 issue of *73 Amateur Radio Today*. The circuit uses parts available at Radio Shack, and will run about \$20. Bill's circuit featured many other useful functions which I deleted from this design to make it a simple one-evening project.

Figure 1 shows the schematic. This meter is based on simple AC voltmeter principles. It picks up the AC voltage from the receiver's FM detector, amplifies, rectifies, and drives the meter movement. The first stage takes the AC voltage from a scanner or your ham rig's discriminator output, blocks the DC, and amplifies it with a gain of three. The next two op amp stages form a clever full-wave rectifier function. The positive half of the input waveform passes around the second op amp to the third, while the negative half is inverted by the second stage,

Photo A. The FM Packet Deviation Meter makes this station complete.

causing a positive output to the third stage. Bill recommends that you not change the values of the second-stage resistors. The circuit is based on the LM-324 op amp chip. It draws about 1 mA total and will last forever on a 9 volt battery. It's very simple to put together on a perfboard. See Figure 1.

Calibration

I've really enjoyed watching all the signals as much as listening to them, and it took a bit of analysis to figure out the best way to use the meter. After several days of monitoring signals over the air, I found that the whole range of the meter is used by various

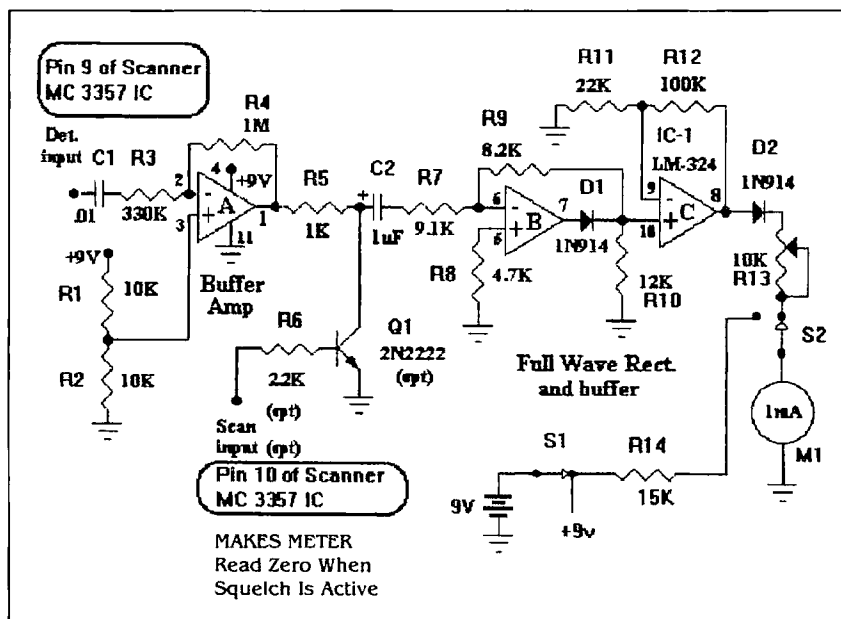

Figure 1. Schematic for the FM Packet Deviation Meter.

Photo B. The FM Packet Deviation Meter with cover removed.

Photo C. The finished product.

packet stations. The really poor ones drive the meter against the 15 reading (over deviation), while no audio of course, drops it down to 0. I chose the 2/3-scale 10 reading as the best calibration setting.

Without a signal present, the discriminator outputs a noise waveform, so the calibration pot on the meter is aligned to center about this 10 reading. Calibration needs to be performed each time the frequency is changed. I usually monitor the frequency for a minute to make sure there is no interference, and then recheck calibration. Any anomaly causes me to change frequency and recalibrate.

When a packet is received, the meter will deflect downward for the good guys and upwards for the bad guys. It's important that you only measure signals that are full-quieting, as noise will throw the reading off. I find it best to keep the circuit portable and take it to the transmitter for alignment. RF is bad news for consistent readings, however. You can avoid this by both removing the scanner antenna and placing a dummy load on the transmitter. If your TNC does not have a variable deviation adjustment (a design defect), the common method is to wire a 10k ohm potentiometer into the audio line to the transmitter. Don't depend on high or low jumpers to operate correctly—these are sucker settings.

After these initial steps, I usually command the TNC into the "calibrate" mode and send the high tone. Another good method is to command the TNC to the "converse" mode and hold down the "return" key. I then quickly adjust the audio pot to my calculated 3 kHz deviation reading (about 8.0 on my meter). Unless you calibrate your meter to a known source you are only guessing about what the readings mean, as each discriminator is different. If you can't find a calibration source, you can listen to signals on the air or tune your station by ear to get an initial estimate. After a couple of days you will quickly come to know what is good and what is bad by monitoring the performance of both your own and other packet stations. The ob-

ject is to get a downward deflection.

Some radios produce a noticeable difference in the two AFSK packet tones. Here, you may want to do the alignment using the more critical high tone. As you might expect, any frequency error throws everything off, so make sure both the meter's receiver and the transmitter are tuned to the same frequency.

Deviation Basics

Whether an FM receiver has a discriminator, ratio detector, quadrature detector, or one of the modern phase detectors makes little difference as long as the output of the detector is proportional to the amplitude of the modulating tone. When a signal is fed to the FM modulator, it varies the frequency directly. The modulated FM signal is a variable set of sidebands whose total bandwidth depends both on the frequency of modulation and the amount of deviation. The limits set by the typical narrow band FM receiver IF stage is about 15 kHz.

The best method of determining the bandwidth of an FM signal is to use a Bessel function chart, as shown in Figure 3. You use this chart to find the number of sideband pairs and then compute the bandwidth. First you calculate the modulation index:

$$P = \frac{D}{m}$$

where P = modulation index, D = peak deviation, and m = modulating frequency.

Then you examine the chart to see how many sidebands there are on each side of the carrier. If the curve comes off the baseline a line-width or more, I include that sideband. The simple bandwidth formulas you find in textbooks are all different and can be considered unreliable. Use the chart. The worst case example is an FM signal that has been deviated 5 kHz with a modulating frequency of 3 kHz. The modulation index is 1.67, giving us four sideband pairs, or eight sidebands of 3 kHz, requiring an estimated 24 kHz bandwidth to contain it. This is quite acceptable for voice when it occurs only briefly. Packet uses a high tone of 2.2 kHz,

and the predicted bandwidth using 5 kHz deviation is a steady 22 kHz. Transmitting a signal with this wide a bandwidth is certain to fail with distant packet stations, and likely even to fail across town. There are two reasons: First, most rigs will clip the audio to limit the deviation, which causes distortion. The second reason is crystal stability. One rig may be tuned 1.4 kHz higher in frequency, and the other 1.4 kHz lower, and still be within crystal tolerance on 145 MHz. This gives us about 12 kHz of worse-case usable receiver bandwidth.

Using 3 kHz deviation results in a modulation index of 1.36, and the chart shows about four sideband pairs, or 8 times 2.2 kHz for a 17.6 kHz bandwidth on the more

Figure 2. PC board pattern and parts placement diagram.

UPDATES

Computer Control For The Ramsey FTR-146

The above article by WD8BNR appeared on page 60 of the March 1993 issue of 73. We printed updates in the April and June issues. With this corrected printed circuit artwork, we hope to have all the bugs out.

Continued from page 20

Corrected PC artwork for the Computer Control for the Ramsey FTR-146.

The Noise Remover

See the above article by K8MKB on page 12 of the November 1992 issue of 73. In some installations, the circuit shown in Figure 3 breaks into oscillations.

Change R1 from 47k to 100k, and R3 from 680k to 470k. Put a 0.001 μ F capacitor across the input side of C1 to ground, and a 0.001 μ F capacitor from point A to ground (across R8).

For more output from the circuits shown in all of the figures, exchange the 0.0047 μ F capacitor with the 0.047 μ F capacitor. The series resistors R5, R9, R12 can be increased up to 4.7k

ohms. If you still need more output take out C3 and C6, and replace C4, C5, C7 with a 0.47 μ F tantalum. The limit adjust pot can be a 10-turn (not 25-turn) 10k pot.

critical high tone, and 12 kHz for the low tone. This reduced bandwidth is much less affected by the frequency drift between stations, and is not distorted by the transmitter deviation limiting circuits. By listening to the audio produced by 5 kHz deviation you will notice that it sounds raspy and terrible, while the 3 kHz sounds very pure.

Conclusion

The recommended setting for packet is 3 kHz deviation. With this meter you can quickly adjust your station, and others, to ensure that the transmitter hasn't gone into limiting, and that the bandwidth is optimized for the typical receiver. By spending a little time tuning up, you will benefit the entire

PC Pakratt for Windows

Love at first byte.

Advanced Electronic Applications, Inc.
P.O. Box C2160
2006 196th St. SW
Lynnwood WA 98036
Telephone: (800) 432-8873
Price Class: \$129

By the time you read this, Pakratt for Windows (PPWIN) should be shipping—finally! It's been a long time, but, if you use Windows and own an AEA controller or TNC, you'll be glad you waited. The product I looked at was marked "preliminary," but it was pretty much the product that will ship, with a few rough edges still there. The fact is, even in this pre-release state, I prefer to use this product over any

ham radio digital communications software on the market.

The Next Generation

I used PPWIN to control the new PK-900, which you will find reviewed elsewhere in this issue. Together, these two make a truly state-of-the-art digital station for the avid operator. Think of PPWIN as a very-pleasant-to-use soft front end for AEA controller

hardware. It doesn't offer features found in other terminal programs like LAN-Link or PK-Gold—it wasn't designed to. Instead, you will find it an excellent replacement for learning the multitude of command line incantations required to make the hardware do all its tricks, and it offers the very user friendly Microsoft Windows environment.

PPWIN really knows AEA hardware. Through easy-to-use combo boxes—ed-

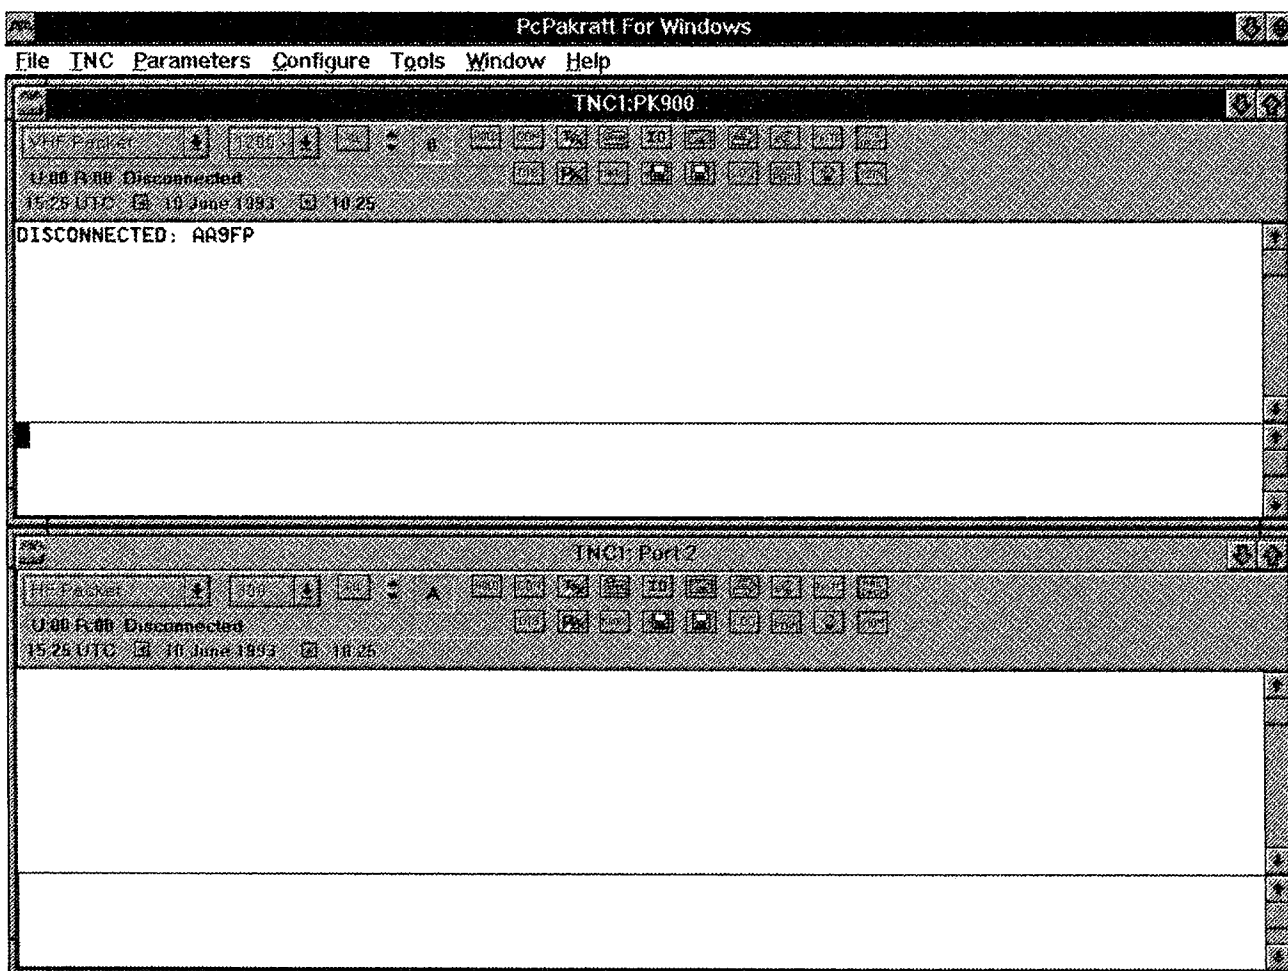

Figure 1. From Pakratt for Windows' main screen you can do just about everything your AEA controller is capable of.

itable fields with drop-down lists—and directly accessible buttons, PPWIN lets you control every aspect of any AEA controller. Forget hours with the manual trying to figure out everything your new controller does: With PPWIN all the options are right in front of you—or a few mouse clicks away.

The Main Screen

At startup, PPWIN greets you with a blank gray window and a menu bar, typical of any Windows application. The first step is to configure the program using the aptly named Configure menu. PPWIN can handle two different controllers, called TNC1 and TNC2. These can be any AEA product, from the top-end DSP-2232 to the budget-level PK-88. Selecting TNC1 from the Configure drop-down pops up a second menu which allows you to set various parameters relating to the controller.

Set Color

This option invokes a dialog box which can be used to set the text colors for text messages displayed in the TNC1 window when it is visible. Different colors can be set for text depending upon whether it is received, echoed, or a message from the controller. These color schemes can be different for each of the controller's virtual channels. This is a very useful feature for

those who run multiple connections.

TNC Configuration

This menu option offers access to the communications parameters used to talk to the controller, and allows the specification of a particular model. It also provides an array of check boxes for selection of initialization options.

Program Files

This option provides a way to specify files used by PPWIN for messages and other use. The files are specified by DOS path name, and push-buttons invoke standard browse boxes to help locate the desired file. There are quite a few files settable from this dialog box:

AMTOR Connect File
Buffer File
Port 2 Buffer File
Capture File Default
Macro File
Maildrop File
TNC Parameter File
Packet Connect File
PACTOR Connect File
QSO Log File
QSO Default File

Program Configuration

This dialog lets you specify a macro to execute at startup, and one for exit—a nice feature. This can save a lot of trouble if you normally do several things at either time. Also available in this box are the buffer sizes for each port (this defaults to 64K), and check boxes to decide whether one or both controllers will automatically open on startup.

QSO Log Defaults

This dialog offers fields for default entries in your QSO log. You can specify rig, antenna, frequency, and power. These can be overridden at logging time.

Opening a TNC

Once you have specified the various parameters you are interested in—the only required ones are in the TNC Configuration dialog—the TNC menu on the main menu bar will show the hardware you configured. Selecting either TNC will open and initialize your choice. If you have a two-port unit, like the PK-900 used to test the program, port 2 will be an additional choice on this menu. By cleverly using the controller's host mode, PPWIN can let you access both ports concurrently—each with its own visible window.

PPWIN opens a window for each con-

CIRCLE 49 ON READER SERVICE CARD

trailer or controller port that is opened from the TNC menu. Each of these windows has a gray bar at the top, with various combo boxes, buttons, and status windows. Below are two panes with scroll bars, one for received text and messages from the controller—the other for locally typed text. This is where you communicate with other stations, but not with the controller itself. Herein lies one of my wish-list additions to the program. Those of you who, like me, are used to operating controllers in a command-line fashion will probably find yourselves typing things like MH and C AA9FP. These just won't work, since anything you type goes out on the air. I wish that AEA had included a command-line window where direct controller commands could be typed—sometimes command line is just easier.

The initialization process will be familiar to those who are current Pakratt users. A small box shows each parameter's name as it is set. The time required for the process can be greatly reduced by checking the Fast Initialization box in the TNC Configuration dialog.

Controller commands are all sent through the combo boxes and buttons at the top of the window and, to be honest, I would much rather have just these, rather than only a command line. On the left-most side of the

control bar is a combo box to select operating mode. Pressing the down arrow on this box drops down a list of all operating modes available for the controller/port that is active. Choosing one instructs PPWIN to set the controller for operation in the select-

"One of the nicest things about PPWIN is the push-buttons that give you immediate access to your controller's functions."

ed mode, including the modem and shift required. Just to the right of the mode box is another combo box which selects data rate. This works the same way and displays the available rates for your hardware.

A set of push-buttons and a small box directly adjacent to the mode and data rate controls provides a way to select the virtual channel to be monitored. It is possible to select all channels or any particular channel.

Directly below these three controls are the status line and time/date. The status line displays messages appropriate to the operating mode—with information like unack'd and received frames, and the state of the link. The date and time are displayed just below the status. The time appears in UTC (Coordinated Universal Time, also known as GMT—Greenwich Mean Time) to the left, and local 24-hour format time to the right of the date. Two small buttons allow you to select the desired version of the time, whose color switches to red when chosen.

Push-Button Operation

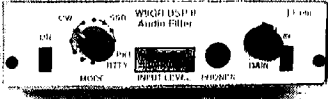

One of the nicest things about PPWIN is the push-buttons that give you immediate access to your controller's functions. Some buttons do something immediate, like the one that turns on the mailbox—AEA's term for mailbox—and the CONPERM button that makes the current connection permanent until you turn it off. Most other buttons produce dialog boxes that give you an easy way to do things that otherwise would require multiple command lines or tedious linear input.

Connect

The Connect button produces a dialog with an editable field, a list box, and six but-

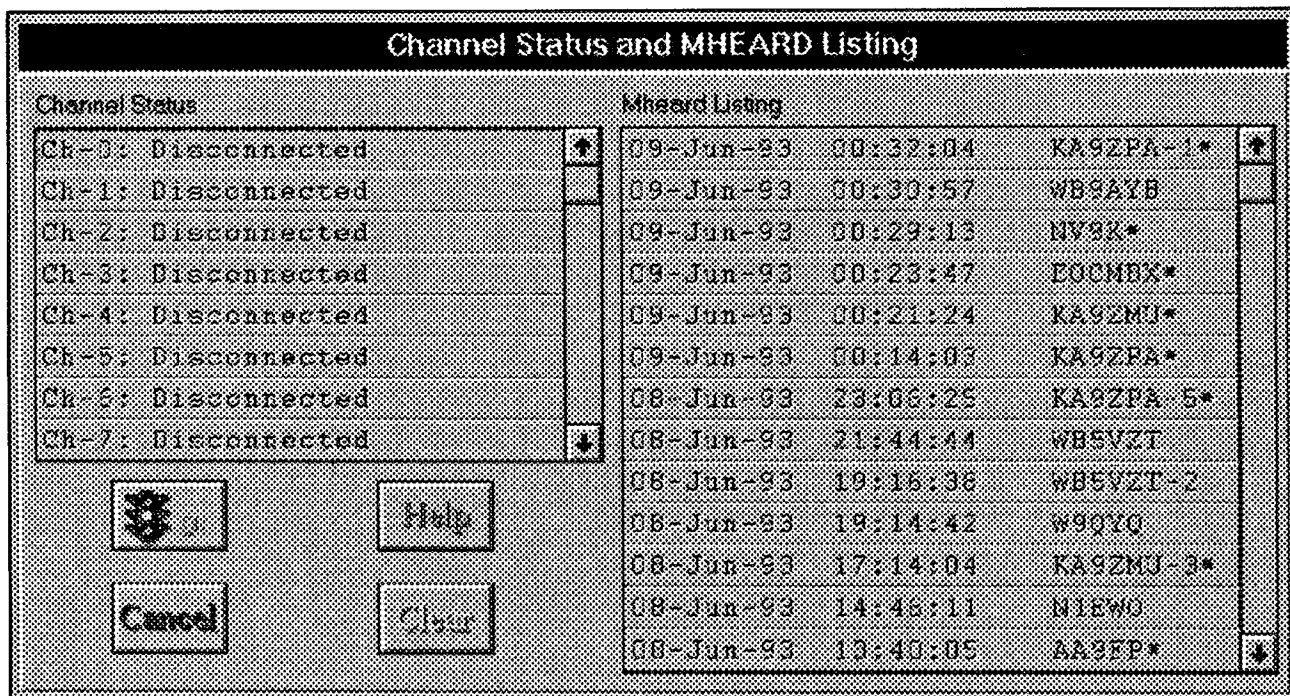

Figure 2. MHEARD dialog box.

tons. The field at the top of the box is where the desired connection gets specified. This can include digipeaters, and the line is specified in the traditional fashion:

N1EWO V AA9FP, EOC, BED (for example)

This is just as a command line would work, but with PPWIN you need only type the connect string once. At that point you can press the Add button, which will add the string to the list box, from which you can select the connection in the future. A companion Delete button allows removal of any strings from the list. The dialog also includes a Disconnect button, should you want to close an existing connection or one in the process of being made. The other three buttons include the usual Close, OK, and Help buttons.

The Help button, as the Help menu option and any other help button in another dialog, launches the standard Windows on-line help system containing the entire manual for PPWIN, as well as a complete listing of AEA controller settings. This is a great feature! Pressing a help button in any dialog produces instant context-sensitive advice—no scrounging through manual pages. As is usual with Windows help, you can search the text for keywords allowing quick and easy access to the information—this feature alone would have value as a separate product.

A companion Disconnect button is located just below the connect button on the main button bar for easy access.

File Transfer

The File Transfer button features a file folder with "XFER" on its side—pretty easy to locate. This button makes moving files

between stations a snap, and not just text but binary (program, data, etc.) files, too. Pressing the button produces a dialog box with several buttons and a list box. A nice feature of PPWIN's file transfer capability is background operation. It is possible to start a file transfer—ASCII or binary—and switch to a different virtual channel to carry on a conversation. This is very convenient, given the relative slow transfer rate of most packet operations.

As with the Connect dialog box, PPWIN maintains a list of file names which can be added to, deleted from, or selected from the list box. Radio buttons—mutually exclusive push-buttons—select send or receive binary, or ASCII transfer modes.

Capture

Text capture, too, is just a button press away—indicated by a right-pointing arrow aimed at a floppy disk. This button produces a simple dialog box with a place to type in a file name (the default name is specified in the configuration menu), a Find button which allows browsing for a specific file, and a pair of radio buttons that select overwrite or append modes.

Printing

A Print button turns on and off capture to the printer. As with all Windows applications, printer setup is on the File menu.

MHEARD List

A button sporting a small ear produces the Channel Status and MHEARD Listing dialog box. This list serves two purposes. First, it shows recently heard stations—just as you'd expect. The surprise is that each entry on the list forms a push-button; push-

ing it—plus OK or Enter—will automatically connect you to that station. This is a great feature—no more scribbling down the info so you can try to connect to a new station that shows up on the list.

This dialog also shows a list of all virtual packet channels, and whether they are currently connected. As with the MHEARD list, selecting a channel from the list allows you to switch directly to that channel.

Maildrop

The Maildrop button makes maintenance easy. Pressing the button, marked with an addressed envelope, invokes the maildrop dialog. This dialog offers a list of incoming messages at the top—a double click will read the message into a pane just below where it can be scrolled using standard Windows scroll controls. Once the message is read, push-buttons offer several options:

Save Message—An editable field specifies the file name, a press of the Save Msg button writes the current message to that file.

Kill Message—The Kill button deletes the message from the Maildrop, just like typing kill {message number} at the command line.

Edit Message—This button invokes a small dialog which allows the editing of various message parameters and status. Three edit boxes offer the From, To, and BBS addresses for editing. Six radio buttons set Private, Traffic, and Bulletin status—as well as Reverse Forward, Read, and Not Read.

A dialog built into the bottom of the Maildrop dialog allows the composition of a message. Fields for Subject and Callsign

specify message parameters. The text is typed into a pane below and edited, or a filename can be specified or browsed as the message.

Macros

PPWIN has so many useful features that I find myself wanting to say, "This is a great feature!" over and over. So, at the risk of repetition—this *is* a great feature. Macros are used by PPWIN in two basic ways. First, there are standard macros for various operating modes. In AMTOR, for example, there is a CQ-AMTOR macro which you edit to contain your personal CQ text. The other type of macro is one you can choose from a listbox by pressing the Macro button from the main bar.

This dialog lets you create your own macros, which can be used to send special text and to control some controller functions. This is not the intention of the macros, unfortunately. To accomplish this, the function that you are interested in must have a keyboard shortcut and you must use a separate editor to get that shortcut as text. As an example, CTRL+F, in AMTOR mode, stops transmitting and sends a Morse ID. To include this in a macro, several steps are required:

1. Launch Windows Write—the Microsoft-supplied word processor. PPWIN

actually makes this easy: It appears on the Tools menu of the main menu bar.

2. While holding the ALT key down, type 06 on the numeric keypad—not the number row of the main keyboard. Then release ALT. CTRL+F has an ASCII value of 6; Windows needs the leading 0. A box will appear in the Write window. This is a place holder for an unprintable character.

3. Using the mouse, carefully select just

"Another thing that PPWIN does to make a ham's life easier is provide a way to easily set all those parms that make or break your station."

the box. Using the copy option from Write's Edit menu, transfer the character to the Clipboard.

4. Return to PPWIN's macro edit Window and Paste the copied CTRL+F in—the SHIFT+INSERT key combo will do this.

You now have a CTRL+F in your macro. While this works, it's no fun. The next ver-

sion of PPWIN needs improvements to the macro capabilities.

All Those Pesky Parameters

On the main menu bar, the Parameters menu offers a way to set parms for each operating mode separately. Each choice provides a dialog with each parm available. Depending upon the nature of the parameter, it can be changed with a push-button, a drop down list, or an editable field—and they are all right there in front of you. To top it off, help is just a button press away. This is not only a great way to set the parameters, but it's a great way to learn them, too.

More and More . . .

As much as I have written about this product, there is more to it. There is a lot of depth to PPWIN, which is really designed to make operations easier. It is not wart-free, but it is, in my opinion, the best way to do digital ham radio I have ever seen, especially when teamed up with a PK-900 or DSP-2232 and their state-of-the-art capabilities. PPWIN will not be everything to everybody, but I can say that I feel a little sorry for those of you who don't own AEA hardware, since you need it to run this great program. If you own a Windows-capable computer and an AEA TNC or controller you have to own PPWIN!

THE POWER STATION

The POWER STATION is a 12V x 6.5 AmpHr gel-cell battery complete with voltmeter, wall charger and a cord for charging via automobiles. It will power most HT's at 5 Watts for 2-4 weeks (depending upon how long-winded you are). Also VHF, UHF, QRP, or HF, mobiles such as the KENWOOD TS-50 (at 60W). There are no hidden costs, all you need is your mobile or HT power cord or cigarette lighter adapter.

The POWER STATION provides 12V from a cigarette plug and has two recessed terminals for hardwiring. A mini-phone jack with regulated 3V, 6V, or 9V output can be used separately for CD players, Walkmans, etc. THE POWER STATION can be charged in an automobile in only 3 hours, or in the home in 8 hours. The charger will automatically shut off when the battery is completely charged, so you can charge it even when it has only been slightly discharged, (unlike Ni-Cads that have memory). Our charging circuit uses voltage sensing circuitry, other brands are timed chargers which always charge the battery a full cycle, this damages their battery and shortens its' life if it only needs a partial charge. The POWER STATION has a voltmeter that shows the exact state of charge of the battery, not worthless idiot lights that tell you "YOUR BATTERY IS NOW DEAD." The voltmeter can even be used to measure voltages of other sources.

One of the fringe benefits of becoming a ham is watching the evolution of modern electronic technology. We hams have a front-row seat at the electronic stage—and sometimes we even get to perform. For example, it wasn't too long ago that a 2m handheld with frequency switches instead of crystals was a big deal. Nowadays, if you don't have dual bands, 97 memories, full-duplex, an alarm clock, and musical access tones, you're just not up to speed! In any product, if you look closely enough, there is always a spot in time where the engineers obviously accomplished the main goal, and then were able to concentrate on adding "frosting" for making the user more comfortable. Once the product has reached the point of fastest/smallest/most powerful/most sensitive, it starts to get more "humane." These features may take the form of memories or scan functions in our handheld, or more intuitive controls or menus. The radio doesn't really transmit any better than that old rock-bound rig, but it starts to make life easier—which is really the main job of any piece of technology.

This whole concept of "user-friendliness" is more often seen in consumer items—ham rigs, computers, cellular phones—than in

electronic test equipment. This is mainly due to the number of units sold, the profit made, and consequently the dollars pumped back into R & D. In light of this, it's impressive to see a low-cost piece of test equipment that has made the jump over to "user friendly."

It's User Friendly

The STARTEK ATH-15 Pocket Sized Frequency Counter comes from a long line of counters that, over the years, have been getting smaller, and faster, and able to read higher and higher frequencies. The engineers at STARTEK obviously found themselves at the same point as their consumer electronics counterparts. The last model out was certainly small enough—any smaller and you'd have to strap it to your wrist. It counted every frequency that most hams were interested in. There was a full line of accessories. The only other improvements could be in the category of "you know, it would be kinda nice if it did . . ."

The STARTEK engineers took this assignment seriously and came up with two new features that make the ATH-15 not just easy, but actually enjoyable to use.

The first feature actually has

nothing to do with frequency counters. It's an LED bar graph signal strength meter. This 10-segment graph sits near the top of the display, and simply indicates relative field strength. By itself, this is a useful item for antenna testing, foxhunting, or checking for RF leaks around your operating console. Used in conjunction with the counter, it provides an easy way to get a handle on maximizing the input to the counter when using low power sources. Rather than waiting for several counts until things stabilize and hoping for a good reading, you can simply peak the LED bar graph and know that your signal is at max—or relocate the counter or RF source until it is. This combined feature is very useful when playing with flea power transmitters, or snooping on a weak signal. (It should be noted that even though the counter and field strength meter can be used at the same time, they are electrically two separate devices. Some products on the market use a signal derived from the counter's circuitry for a strength indication. This works, but the signal strength readings can be dependent on the gate time of the counter, and whether or not it's in the HOLD mode. The ATH-15 keeps these functions separate, providing a true real-time field strength meter—at no extra cost.)

The second feature is actually several features, but they all culminate in the Automatic Trigger and Hold circuitry. This feature is extremely impressive, especially considering the price tag on the unit. Put simply, the readout will hold and display the last properly received frequency. In other words, keying your portable for a second on channel one will cause that frequency to stay on the display. Flip to channel two and tap the PTT. The display will flip to channel two's frequency—and stay there. This is a great

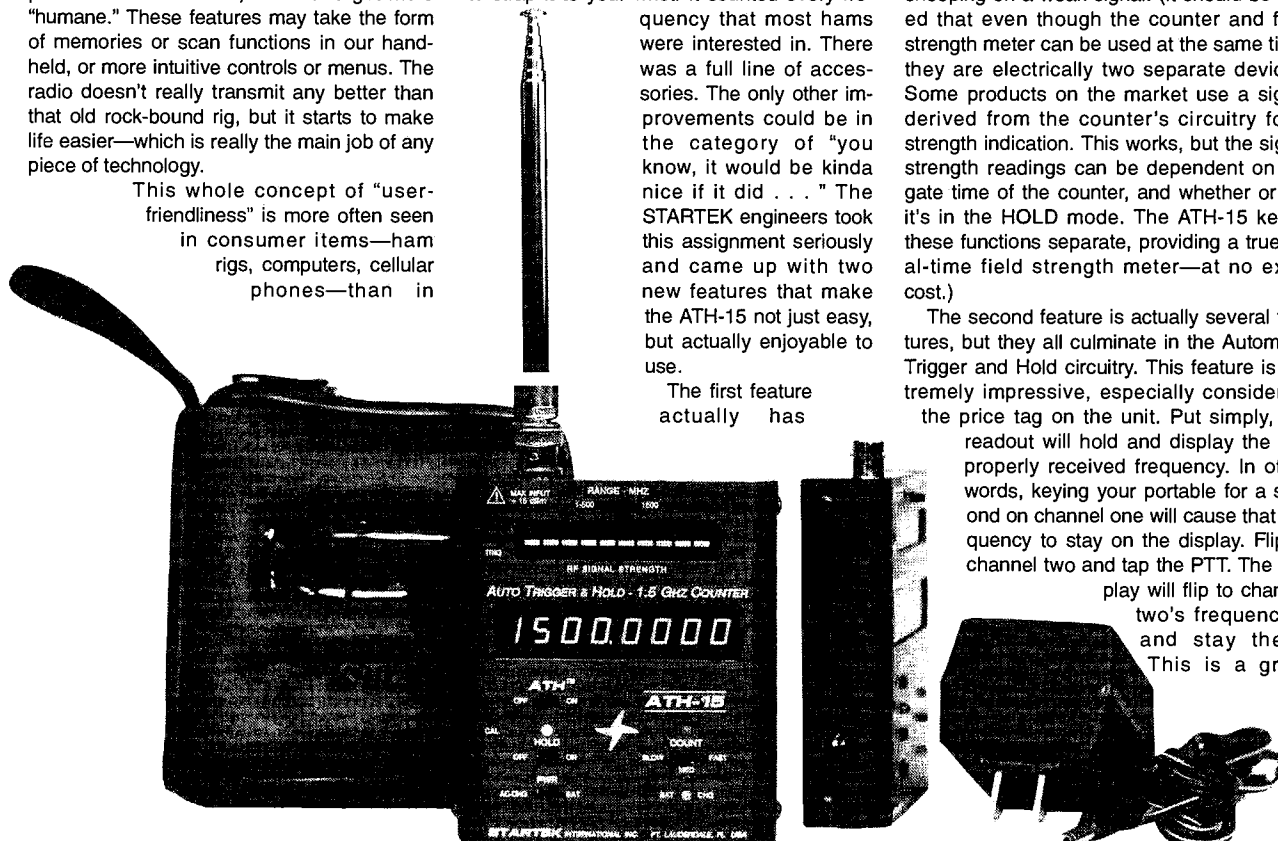

Photo A. The STARTEK ATH-15 Portable Frequency Counter.

function for testing or checking out multi-frequency radios, or counting and storing an interfering frequency. (If the optional "One-Shot Trigger" and "Hold" options are purchased, the ATH-15 will display and lock onto the first readable signal, ignoring any that follow.)

Just as important as the Automatic Trigger and Hold capabilities are the functions that make it possible. The first of these is an amazingly quick count time. The specs say that the unit can read an input signal, display the frequency, and switch to HOLD status in less than 80 milliseconds. In reality, 80 milliseconds seems like the point somewhere between where you decide to push the PTT and where you feel any pressure at all. (Plan on spending the first five minutes with your new counter running around the house, keying up everything in site. When I showed off the review unit to friends and technicians, the common term to describe the response time was "Wow.")

The other feature of importance is the "Automatic Clean Dropout" function. This keeps an eye on the current frequency and compares it to the last count. If the current count is of a shorter duration, the unit hangs on to the last good count without updating the display. This means that the "held" frequency will probably be correct—no "garbage" counts are displayed from when the transmitter was keying.

The ATH-15 is a sensitive unit. Most hand-

helds could be detected out to about 100 feet with no problem, using the standard antenna. The problem with this sensitivity is that the unit is easily overloaded in strong multiple RF fields. This is due to a combination of the unit's 1 to 1500 MHz bandwidth, plus its high sensitivity. Unlike a radio with a tuned front-end, the ATH-15 can be listening to several signals in addition to the one you want to count. In other words, if you want to copy a weak 146 MHz signal at the same time the ATH-15 is hearing a garbage truck on 30 MHz, the police on 155 MHz, a construction company at 450 MHz, and a cellular phone at 850 MHz—well, things can get confusing. This "swamping" is the nature of any broadband device, as any ham who's had his HT at a flea market can tell you. The STARTEK engineers have created a solution to this in the form of a set of three different bandpass filters. These half-inch diameter filters come with BNC connectors, and pop in-line with the external antenna. They filter out the undesired frequencies, while passing the band you might be interested in. The filters are available in 60 MHz low-pass, 400 MHz high-pass, and 800 MHz high-pass configurations. They greatly increase the "effective sensitivity" of the unit, and would be helpful if you tend to do off-the-air monitoring of specific channels or bands. For most general purpose applications the filters won't be needed.

Operation of the ATH-15 is similar to earli-

er members of the STARTEK family. The "Count" switch controls the speed at which the samples are taken. As normal, a slower count time gives you a higher resolution display (five decimal places when counting a 1 to 500 MHz signal in the "Slow" position). The unit has a manual hold switch for locking in a reading, and of course the Automatic Trigger and Hold function can be turned on or off. If the "One Shot" option is purchased, switches on top control the resetting and operation of this mode. Like other models, this unit has two band positions: 1 to 500 MHz, and 500 to 1500 MHz. New features include a low battery indicator and extra bright LED digits.

In addition to the basic unit, STARTEK offers a complete line of accessories including antennas, cases, a high-stability oscillator option, and the bandpass filters. (Due to its size, the ATH-15 will tend to spend a lot of time in the toolbox or on the dashboard. The optional case is highly recommended.) At press time, the ATH-15 was being offered at a promotional price of \$199, and a new model, the ATH-30 (2.8 MHz capability), was introduced at \$259. They come standard with the one-shot feature. Prices include NiCd's and a charger, and a one-year labor, five-year parts warranty. Your requirements concerning range and options might vary, but any of the STARTEK counters represent a great value for your test equipment dollar.

ID-8 Automatic Morse Station Identifier

Compatible with Commercial, Public Safety, and Amateur Radio applications. Uses include Repeater Identifiers, Base Station Identifiers, Beacons, CW Memory Keys, etc. Great for FCC ID Compliance.

- Miniature in size, 1.85"x1.12"x0.35"
- Totally RF immune.
- All connections made with micro-miniature plug and socket with color coded wires attached.
- CMOS microprocessor for low voltage, low current operation: 6 to 70 VDC unregulated at 10mA
- MOS distortion: low impedance adjustable sine-wave output: 0 to 4 volts peak to peak
- Crystal controlled for high accuracy
- Transmitter PTT output (to key transmitter while ID is being sent), is an open collector transistor that will handle 80 VDC at 300mA
- Field programmable with SUPPLIED keyboard
- Confirmation tone to indicate accepted parameter, plus tones to indicate programming error.
- All programming is stored in a non-volatile EEPROM which may be altered at any time
- Message length over 200 characters long
- Trigger ID with active high or low
- Inhibit ID with active high or low. Will hold off ID until channel is clear of traffic.
- Generates repeater courtesy tone at end of user transmission if enabled
- Double sided tape and mounting hardware supplied for quick mounting
- Operating temperature range: -30 degrees C to +65 degrees C
- Full one year warranty when returned to the factory for repair
- Immediate one day delivery.

Programmable Features

- Eight programmable, selectable messages
- CW speed from 1 to 99 WPM
- ID interval timer from .99 minutes
- ID hold off timer from 0-99 seconds
- CW tone frequency from 100 Hz to 3000 Hz
- Front porch delay interval from 0 to 9.9 seconds
- CW or MCW operation

\$89.95 each

programming keyboard included

73 Review

by Jeffrey Sloman N1EWO

The AEA PK-900

State-of-the-art digital ham radio.

Advanced Electronic Applications, Inc.
P.O. Box C2160
2006 196th St. SW
Lynnwood WA 98036
Telephone: 800-432-8873
Price Class: \$569

The dual-port PK-900 represents the next evolutionary step in AEA's multi-mode controller technology. Unlike the revolutionary DSP-2232, the PK-900 uses traditional modem technology with a few high-tech twists. The PK-900 offers improved ease of use and some changes in the computer-controlled portions of the unit's circuitry.

LCD City

Unlike previous models—even the top-of-the-line DSP-2232—the PK-900 sports a sexy new LCD annunciator panel in place of the traditional LED Christmas light display. This high-contrast, backlit panel is easy to read under most lighting conditions, (with the exception of some occasional glare from reflected light.) One thing that makes this new display particularly useful is that, unlike the LED arrays of previous models, these indicators say just what they mean. The operating mode of either port can be seen from across the room—no more memorizing LED locations or guessing. The display provides a lot of information: operating mode, link state, TX and DCD indicators, various status indicators and, at the bottom of the display, a tuning meter.

Those of you interested in HF modes have, no doubt, spent a lot of time in front of your controller's tuning meter trying to get those LEDs to look just like the picture in the manual. I have, too. To be honest, my first reaction to the new LCD version was not good. It is quite different to use than the LEDs I had come to know. But after I had used the 900 for a while I found the LCD just took some getting used to. It is at least as good, if not better than, its predecessor. At the very least, it is physically wider, making it easier to see.

Note that the 900 display has only fixed annunciators, it does not have the ability to display arbitrary text messages like its DSP-2232 big brother. While this would be very nice to have, it really does detract from the 900's utility.

Also located on the front panel are the traditional threshold control (a nice, big, easy-to-use knob) and the power switch. This knob adjusts the sensitivity of the DCD (Data Carrier Detect) function, and is only functional for port 1. Moving the power to the front is a nice change from the PK-232, the 900's predecessor.

Photo A. The AEA PK-900.

The Back Panel

The back panel of the unit is a pleasant blend of the old and new. The 900 uses the same coaxial power connector as previous models, making upgrading a little easier. A five-pin DIN connector provides output for a tuning scope, and for direct CW keying.

This connector replaces the old RCA jacks for keying, although I'm not sure this is an improvement. The RCA approach was very easy to use.

The two radio ports depart from the PK-232 and more closely resemble the DSP-2232's five-pin DIN connectors. The 232's unusual radio connectors made building a cable somewhat difficult once the AEA-supplied units were exhausted. A pleasing throwback to the 232, however, is the inclusion of two 1/8-inch phone jacks on the rear for audio input. This is great for SWLs who will not transmit with the unit, and for those of you who are like me and just can't wait to see the unit do its stuff.

A fourth DIN connector provides FSK (Frequency Shift Keying) outputs for RTTY fans with radios capable of using them. Both positive and negative keying are available. Transmit level controls for each radio are screwdriver adjustments, also located on the back panel.

The connection from the PK-900 to a data terminal or computer is made through a DB-25 connector which supports pins 1 through 8 and 20. These are the standard pins needed for any sort of RS-232 serial connection. Next to this connector is the unit's reset button, which operates in conjunction with the power switch to reset the 900 to factory defaults.

Four additional trimmers located on the right side of the box allow screwdriver adjust-

ment of the AFSK levels for each radio. The PK-232 had only one, pointing out that the 900 is a true two-port unit, not just able to switch between radios.

What Can It Do?

The specifications of the PK-900 are impressive. The unit will operate in just about any mode that a modern ham could want:

- AX.25 (Packet) HF and VHF
- Baudot RTTY
- ASCII
- AMTOR
- FACTOR
- Morse (send/receive)
- HF Wefax (Weather Fax) in Greyscale
- NAVTEX reception
- TDM (Time Division Multiplex) reception
- Bit-inverted RTTY (encrypted) reception

The PK-900 accomplishes all these modes with some very nice hardware. AEA has always been known for superior HF performance, and the PK-900 incorporates the same eight-pole Chebyshev bandpass filter used in the excellent PK-232 for high frequency operations. This filter means that the 900 should do much better than average with poor signal conditions, an assertion borne out by experience—not just mine; ask around. The 900 has it all over the PK-232 in the modem department, since soft selection of the modems let each mode's precise needs be accommodated.

On the output side, the unit uses a DDS chip (Direct Digital Synthesis) to modulate the radio making it extremely flexible. The PK-900 could produce any sort of modulation you might want, including DTMF or two-tone sequential paging, if the mood struck you. A user program capability makes this feature

available to the hackers among us.

With its optional 9600 baud modem (about \$75), the PK-900 is ready to keep up with the world of packet as it grows. By the time you read this, PACTOR will be a standard feature, no longer an option. Current owners without PACTOR should contact AEA concerning the upgrade.

Dual Port

The big question I hear about the PK-900 concerns its dual-port capabilities. Hams want to know just what it can do with the two ports. Here's the scoop: Radio port one can do anything—any mode the controller is capable of. Port two, on the other hand, is restricted to packet—HF or VHF. This is full simultaneous operation. Unlike the PK-232 whose two ports were selectable by a switch, the PK-900 can keep your VHF packet station on the air while you work AMTOR, or PACTOR, or any other mode on port 1. To me, this is what dual-port ops should be. Keep in mind that AEA's engineers designed this box to be used in the shack, not as a node in a packet network. Its features and capabilities are targeted to that market.

PACTOR

Yes, the PK-900 does PACTOR. This mode is a lot of fun, combining the qualities of packet and AMTOR for excellent weak-signal performance. The PK-900's inherently ex-

cellent HF performance is available in PACTOR mode, too. You will find plenty of PACTOR traffic on 10 and 20 meters. It sounds like an AMTOR station on barbiturates. This mode will probably eventually replace AMTOR, since it works better for most amateur operations.

Using the 900

If you are familiar with AEA hardware, the PK-900 will not present any surprises. The unit's autobaud routine easily sets the data rate at initial startup, reducing a lot of difficulty for new users. The manual provides a thorough section on setup and connection of the unit. Once again I am forced to say that, while AEA's manuals contain lots of information, their organization affects ease of use a little more than I would like. (A diplomatic way of saying I don't care for the manual.) On the other hand it does include the most important information: connector pinouts, schematics, and a complete command summary.

In my opinion, there is only one way to use the PK-900: with AEA's new PC Pakratt for Windows. This program, which is reviewed elsewhere in this issue, makes using the PK-900 a real pleasure. Not only does PPWIN know about every bell and whistle, it also provides concurrent access to the two radio ports—a neat trick. If you can't run Windows, you should seriously consider buying a pro-

gram that knows about the PK-900. There are DOS and Macintosh versions of Pakratt available from AEA, as well as third-party terminal programs that work with the unit. While the 900 can be operated from the command line, it is a complex piece of equipment and will have a very steep learning curve without the computerized assistance.

Performance

What else can I say? The PK-900 performs very well. It is directly comparable to the PK-232. In fact, in side-by-side testing, the two units were indistinguishable. Both showed excellent HF performance—especially noted in poor conditions or with weak signals. VHF performance was stellar as well, but of course it had better be. If a TNC has trouble on VHF packet, something is wrong. If you want some opinions on PK-900 performance, you can ask some PK-232 owners what they think of their controllers—you're bound to find several on the local repeater.

Conclusion

Teamed up with PC Pakratt for Windows and a pair of transceivers, the PK-900 is the heart of a truly state of the art digital ham station. The PK-900 costs a bit more than the PK-232, but the difference in cost is reflected in the capabilities of the box. If the additional outlay doesn't scare you off, you won't be disappointed with the PK-900.

Julieboard

An easy-to-build DDS synthesizer for the PC printer port.

by Bruce Hodgkinson VESJIL

Every so often, a technology development comes along which radically and permanently alters the landscape of amateur radio—spark to CW, AM to SSB, vacuum tubes to solid-state, and so forth. Each of these new developments has made possible things which could only be dreamed of before, but quickly become taken for granted. The introduction of direct digital synthesis (DDS), a DSP-related technique, has been one such advance in the RF design field. At first, DDS-based gear could be afforded only by the military, but the state of the art has now advanced to the point where new commercial and amateur radio designs include it as a standard feature.

Why DDS?

The best way to answer that question would be to take a look at the disadvantages inherent in the old techniques. Traditionally, VFOs (including those based on phase-locked loops) have employed analog LC oscillators dependent on mechanical and physical characteristics for frequency control. Although analog oscillators are appealing due to their apparent simplicity, they fall prey to the usual analog type bugaboos: calibration error, drift, phase noise, excessive lock-up time, etc. This means that designs which use analog frequency control can—and usually do—lead to alignment, debugging and calibration hassles which then require expensive equipment and time to fix. For those working with phase-lock loops, there is the additional problem of making the frequency resolution vs. lockup time vs. capture/lock range tradeoffs, which invariably compromise performance and/or force the designer to go to multiple loops, mixers, filters, etc.

With DDS, on the other hand, a few chips on a board slightly larger than a business card can implement a wide-band oscillator which gives:

- 0 to 16 MHz coverage
- 0.007 Hz frequency resolution
- Virtually instantaneous switching time
- No drift/no calibration
- Excellent spectral quality
- Simple interface via PC printer port

So, I designed one. This board (which I've named the "Julieboard") is easy to build and is intended for use as a building block to add digital tuning capability to home-brew equipment.

Why the PC Parallel Port?

The first part of this question really asks, "Why the PC?" The DOS computer has made its way to a very high number of amateur stations, doing such jobs as log-keeping, packet radio, word processing, satellite tracking, et cetera. The price has come down to the point where (occasionally) first-generation PCs are actually available free for the taking if one is at the right place at the right time! The software required to drive this oscillator is so simple that it will run on any DOS machine, right down to the humblest one-floppy system, which means that if a PC actually has to be acquired for the specific purpose of running this oscillator, it needn't cost more than a nominal amount.

The second reason for using the PC is that it is a fine platform from which to develop and implement control functions via software: The "front panel" can take any form the user wants, changes can be made at will without having to modify or junk hardware, and functions can be

easily done which would be difficult, if not impossible, to do with dedicated hardware. Rather than being stuck with one hard-wired approach, the user has a software "playground" in which his only limitations are imagination and time available for programming.

Finally, code can be written, modified, and debugged on the same machine on which it runs—allowing the use of widely available and reasonably priced development tools.

The second part of this question is, "Why the parallel port?" Why not do a plug-in (slot resident) version? The first answer is that not all PCs (lap-tops, for example) have plug-in slots available for another board. Also, many PC owners, especially those without a technical background, are not really keen on tearing apart a working system just to install another board which then has to be configured and set up on a particular address location. This is a real problem if the PC belongs to somebody else or the oscillator has to be moved often.

The parallel printer port offers a "plug and play" alternative: Almost every PC has a printer port and few indeed are those computer users who aren't capable of guiding a DB-25 connector onto the end of a cable. Also, a plug-in board approach forces the user to install the oscillator inside the PC itself—which can cause noise problems, as well as impose limitations on where the equipment can go. With the parallel port approach, the equipment can be located a long distance away from the PC and driven via a long extension/ribbon cable for remote operation. Finally, the parallel port, being non-bus-specific, can be replicated with any simple TTL six-bit register. For example, there is no reason why an appropriately programmed single chip microcomputer (such as a Motorola '68705 or Intel '8051) couldn't replace the PC for those who really object to having to drag around a large, bulky PC just to drive a tiny little board. With a single chip microcomputer, an entire HF rig could be made to fit into a shirt-pocket-sized package!

Circuit Description

The circuitry for the Julieboard fits on a small two-layer printed circuit board about 2.5" x 4.5". On one end is the DB-25 connector for the printer cable and the other end has the BNC output and power/external-clock connectors. Power input needs are not critical—anywhere from about +7 VDC to +12 VDC will do. The input is polarity-protected so if the polar-

Photo A. Julie and her board.

ity is wrong, no damage will be done—it just won't work. The incoming DC voltage is regulated down to the +5V level required to run the on-board logic. The only restriction regarding input voltage is to keep it high enough to overcome voltage regulator dropout and low enough to keep regulator power dissipation at a reasonable level. (This circuit draws about 200 mA and the difference between the input voltage and +5V output is dumped as heat at about 200 mW per excess volt).

The largest IC, a 28-pin DIP package (a Harris HSP45102) contains the actual DDS synthesizer logic right up to the sine PROM-output. This device is clocked at a 40 MHz rate by a clock oscillator module and produces a new 12-bit binary word at its output pins every clock cycle. The frequency increment is determined by a pair of internal 32-bit shift registers which are loaded via TTL bit-sequences driven from the parallel port.

The 74HC14 is used as a buffer between the "outside world" and the Harris DDS chip—it provides input signal conditioning and serves as a buffer for the more expensive DDS device. Likewise, the 74F132 performs a conditioning and buffering function between on-board logic and the outside world. It performs an automatic line select function for the external clock: If an external clock signal is applied, the board logic automatically selects that signal, saving the user from having to configure any jumpers.

The output of the Harris DDS chip represents a 12-bit binary sample of the desired waveform at the time of each clock tick; before it can be of much use, this binary output must be converted into an analog voltage. The Harris CA3338 video digital-to-analog converter (a 16-pin DIP package) converts the digital outputs into corresponding analog levels at the 40 million samples per second rate. This level of performance was unheard of several years ago and was one of the reasons why DDS systems were so expensive when they first came out. Things have changed.

The output from the DAC looks like a sine wave made up of little tiny "steps"—256 different levels, to be exact. (One small compromise in this design was made by using an eight-bit DAC rather than a 12-bit DAC, but the four "wasted" binary outputs have such a small impact on the output that the savings in cost easily justified the change. With the 12-bit DAC, the sine wave would be made up of 4,096 different levels of steps.)

"Wait a minute," one might say, "That's noise—I don't want THAT on my transmitter output." Without getting too deeply into sampling theory, let me say that "that noise," is almost completely insignificant. Look at the "made-out-of-little-steps" sine wave again. Think of this as an absolutely perfect sine wave with a superimposed noise consisting of those steps. See how small and how much higher in frequency (than the sine wave) is that noise waveform? It is no problem to filter the noise out—done by the low-pass filter module located on the board.

The filter module implements a seventh order elliptic low-pass filter in a 10-pin SIP package. The space taken by a discrete version of this filter could easily take up half again as much room as the remainder of the circuitry. Since this de-

Figure 1. Simple controller routine written in GWBASIC.

sign is a "building block," why not make it as small as possible?

Driver Software

One of the nice things about using the PC to drive this unit is that a wealth of software development tools are available. The first thing that comes to mind probably would be GWBASIC or some other BASIC interpreter. GWBASIC was used to get the proto-type up and running and a listing of a simple controller routine is shown in Figure 1.

To operate the board, the driver program must drive six DDS control lines:

SDATA* (shift data)
 SCLOCK* (shift clock)
 XFER (new value transfer)
 ENPHACC (enable phase accumulator)
 SHIFTEN (shift enable)
 BANKSEL* (BANK select)

In normal operation, the software holds all four lines HIGH—enabling ENPHACC (allowing the oscillator to run) and disabling/idling the other three (SDATA*, SCLK*, and SHIFTEN). The choice of "HIGH" as the normal state is no accident: This allows the output frequency to be set from the computer, then disconnected from the PC without losing the programming. This

means that the printer port does not have to be tied up permanently—it can still be used to drive the printer while the synthesizer is still in operation by means of a printer switch!

To load a new frequency, the program disables XFER by driving it LOW, enables SHIFTEN by driving it LOW, then shifts in new data by clocking in 64 bits of updated frequency information via the SDATA* and SCLK* lines. Each data bit must be inverted (SDATA* = "0" to shift a "1" into the DDS) and is clocked-in with each HIGH-to-LOW transition on the SCLK* line. The new frequency pair is transferred into the DDS once software re-enables the XFER line by driving it HIGH again. (If this line is allowed to stay active throughout the shift process, there would be 31 periods during which the output frequency would be set to a bogus value, possibly causing interference far off-band).

If desired, the oscillator can be disabled by setting ENPHACC LOW, though this is not critical.

Selection between the two banks is done via the printer port STB* line. This is an open-collector line, so it can be driven from external equipment or from the PC. The PC can read the status of this line, so it can respond to external events via software. For example, a pair of frequencies could be programmed: one frequency

Continued on page 44

Julieboard

Continued from page 42

for "mark," the other one for "space," then keyed to send RTTY.

In a transmitter VFO application, RIT or split frequency operation can be implemented by loading the appropriate transmit and receive frequencies into their respective banks. (This is a good example of software being used to replace hardware.)

If an external line drives this input, it should be a TTL open collector driver so that it does not cause or suffer damage if the computer should drive the line LOW. This "wired-OR" scheme (where if one source or the other or both drive LOW, the line gets dragged LOW) implements an internal drive/external drive scheme which requires no hardware configuration or setup.

Constructing the Hardware

The circuit is not difficult to duplicate and can easily be built with wire-wrap. Because high frequencies are involved, it must be built with the proper techniques or it will not work at all! If you are not familiar with high-speed logic, a commercially fabricated blank PCB or a wired-and-tested board (available from the author) is probably the safest approach.

A high quality circuit board with a low-inductance ground is an absolute must—my standard technique is to use prototype boards with the fat copper strips running up the IC center lines and bridge the strips crossways with a cross-grid built up out of solder-saturated SOLDER-WICK laid along the board. Don't even think of using one of those copperless "protoboards." Plan the layout ahead of time to leave room for the IC sockets and decoupling capacitors.

The IC sockets must be high quality machined gold contact types—the cheap leaf types are not suitable due their high profile (needless lead inductance) and poor reliability. I have often seen them fail, but I've never seen a gold machined contact fail yet. They are expensive (often costing more than the chips they hold), but they are cheap aggravation insurance.

Place the sockets in their final resting places and wire in their ground pins. These must be near zero in length and the widest practical width. My usual practice is to dedicate the bottom-side copper strip (running up the center of the IC pin-rows) to ground and solder the IC ground pins directly to that.

After all, the IC socket's ground pins have been hooked up and the decoupling capacitors have been installed. Decoupling capacitors MUST be placed at the power supply pins of the HSP45102 DDS chip (8,22), the CA3338 video-DAC (13,16), the clock module (14), and the 74F132 (14). The 74HC14 is not a high-speed part, but it should be decoupled also. Keep the leads of the decoupling caps short—the body of the capacitor should just about touch the power pin being decoupled! An eighth-inch lead length is too long. On the DDS chip, the IC designers conveniently placed a ground pin immediately adjacent to each power pin so that the decoupling caps can exactly bridge power/ground with zero lead length—this dictates the use of capacitors with 0.1" lead spacing. Use 0.1 μ F as specified—don't try to "improve" the decoupling by

Figure 2. A) PC top foil pattern; B) PC bottom foil pattern;

using higher values of capacitance: Higher capacitance values tend to be more inductive and have a lower self-resonant frequency. Above its self-resonant frequency, a capacitor looks inductive and could make the situation worse than if it weren't there! Once the decoupling caps are installed, wire up the +5V bus to the sockets. At this point there should be virtually infinite DC resistance between the +5V and ground lines.

Next, install the 7805 regulator and its diodes. A heat sink with thermal compound on the regulator is a must, as it will dissipate about 1-1/2 watts with +12V input and can get hot to the touch. If you know for sure that the input voltage will always be +12V, a 22 ohm 2W series resistor can be placed in the power input line to help drop the voltage and decrease regulator dissipation. My usual rule of thumb: If I can't hold my finger on a heat-dissipating device, it's running too hot.

When building something, it is wise to take a "divide-and-conquer" approach by doing the project stage-by-stage and testing it after each round of construction. This is a good time to make the first test—better to fry one cheap regulator now than a board filled with expensive parts later! Apply power to the unpopulated board and confirm that the regulator output equals +5V and that +5V appears at all power

supply pins and 0V shows up at all ground pins. Check resistances between the ground pins with an ohmmeter to confirm that all "ground" pins are indeed tied to ground. Now, install resistor networks RN1 and RN2 along with U1 and wire up all the signals involving these devices, right up to and including the DDS chip, U2. In the breadboard version, I wired up diagnostic LEDs to the outputs—a great aid for software development and for verifying that the right LPT port is being used to "talk" to the board. Power up the board and probe U2 pins 9, 10, 12, 13, 14, and 17—all of which should be a logic LOW. U2 pins 11 and 18 should be HIGH. Short the following DB-25 pins one by one to ground and look for these responses:

DB25, pin 1	U2, pin 9 goes HIGH
DB25, pin 2	U2, pin 13 goes HIGH
DB25, pin 6	U2, pin 14 goes HIGH
DB25, pin 7	U2, pin 17 goes HIGH
DB25, pin 8	U2, pin 12 goes HIGH
DB25, pin 9	U2, pin 10 goes HIGH

The next phase requires an HF receiver and a PC running the Julieboard driver software. Wire up the oscillator module and install U2. (Bear in mind that the DDS chip is specified as being ESD-sensitive by Harris and can be damaged or even destroyed by improper handling. If possible, handle this chip only at a properly equipped

(B)

(D)

C) PC drilling template; D) parts placement diagram.

ESD-protected workstation with wrist straps and an anti-static worktop.)

The 74F132 NAND gate U5 and its associated parts may be installed now.

Connect the PC to the Julieboard DB25 female connector via an appropriate cable (male DB25/male DB25 straight-through) and power up the board. Select a test frequency (this isn't critical, any frequency between 1 MHz and 16 MHz will do) and tune the receiver (CW or SSB mode) to that frequency. A clear continuous carrier should be audible fairly close to the expected frequency. (Use a short piece of wire in close proximity, but not touching, the board as the antenna for the receiver). Try tuning the signal in

100 Hz increments and listen for the corresponding changes in pitch. If it works . . . congratulations, you're almost there! If not, look for activity on U2 output pins 27-28 and 1-6: If they are completely dead, try verifying the presence of the 40 MHz TTL clock at U2 pin 16 and confirm proper U2 hookup. Check that:

VCC	pin 22 = +5V
VCC	pin 8 = +5V
BANKSEL	pin 9 = LOW
ENPHACC	pin 12 = LOW
LOAD*	pin 18 = HIGH
GND	pin 7 = GND
GND	pin 15 = GND
GND	pin 21 = GND

Try feeling the case of the DDS chip. If it is very hot, the problem likely involves the DDS chip itself; if it is stone cold, the problem could either be a faulty clock module or a dead DDS chip. A normally working DDS chip should be slightly warm—if this is the case, suspect a problem with the programming or control process. (Also check to see if it is getting +5V!).

Once DDS chip operation has been verified, wire and populate the CA3338 video DAC (U3) and the filter module (FL1) sockets, observing the same ESD precautions as for U2. The synthesizer output should look like a perfect sine wave, except for low frequencies which will show some "staircasing," courtesy of the D/A conversion process. Finally, verify the EXTERNAL CLOCK function with an external clock—if it works OK, then the construction of the synthesizer is complete. Have fun with the new toy!

Conclusion

I have had computer-controlled DDS synthesizers in my shack for several years now and would almost rather give up my scope or multimeter than do without them—they were well worth the development cost. So far, they have been used for:

- Frequency spotting
- Software-controlled VFO
- VFO for home-brew direct conversion receivers
- Digital retro-fit to analog equipment
- Remote tuning of transmitters/receivers
- Frequency-hopping/spread spectrum work
- Programmable secondary frequency standard
- Crystal/crystal-filter characterization
- Crystal oscillator substitution
- ATE signal generator/sweeper

I found that direct conversion receiver circuits worked especially well with this oscillator—tuning via software on the computer screen was a real novelty and the sound was particularly crisp and clear. Perhaps the next challenge will be a home-brew digital transceiver!

Personal Note

Why "Julieboard"? Well, back when I did my first DDS-for-a-PC design (this is my third), I needed a name for the project. At the time, my second-oldest daughter, Julie, was in her active toddler phase and the name seemed appropriate for a board originally intended for frequency hopping development work. Since I have three other daughters, I suppose I'll have to do at least three other boards so that Julie's sisters don't feel left out!

3	U1,U4-5	14p machined (gold) IC socket	AE7214

Blank printed circuit boards, partial kits, and finished units are available from the author (Box 232, Pakenham, Ontario, CANADA K0A 2X0; (613) 624-5247).

Last month we introduced the topic of variable capacitors by showing two different types: straight line frequency and straight line capacitance. We examined their different styles of construction. We also looked at two-section capacitors and how they are used to tune doubly-tuned RF circuits and the RF/O circuits of superheterodyne radio receivers. In this month's column we will take a look

Two special forms of air variable capacitor are the split-stator and the differential. The symbols for these devices are shown in Figure 1. The split-stator (Figure 1A) uses a common set of rotor plates, but two sets of stator plates. In other words, it is similar to a two-section variable, but with a common set of rotor plates rather than two sets. The capacitances of each section of the split-stator

The circuit in Figure 2B is an RF bridge that can be used to measure antenna impedance, or at least the resistive component of antenna impedance. The bridge is balanced when the ratio of the two halves are equal, or when:

(where Z is the unknown impedance). Resistor R1 is generally set to the system impedance, typically 50 ohms or 75 ohms. In most amateur radio applications it is permissible to use a 68 ohm resistor for R1 in order to accommodate both 50 ohm and 75 ohm systems with only a small error in each. Resistor R1 must be a non-inductive type, such as carbon composition or metal film. Excitation is provided by a signal generator applied to J1.

Other applications for capacitors such as the one pictured in Photo B are found where all three sections are connected in parallel. For example, the loading control of pi-network output tank circuits (used in vacuum tube final RF amplifiers in transmitters), often require 800-1200 pF of capacitance. The RF voltages are quite low.

because the output impedance (50 ohms) is low, so it is not necessary to use wide "high voltage" spacing for the loading control (in most cases . . . always calculate for any given power level and allow a margin). Another 3X parallel situation is found in LF and VLF receiving antenna loops where high capacitance is needed. Also, some transmitting loops, as well as many receiving loops, use a single turn input/output loop (depending on point of view, RX or TX) to couple a multi-turn loop antenna to the rig. The multi-turn loop can be resonated with a relatively small capacitance, but the single-turn coupling loop typically wants to see a very high capacitance.

Photo C shows a "transmitting variable" that can be used in high power (2 kW) RF power amplifiers and antenna tuning units. What makes this a "transmitting" variable is the wide spacing between the plates. Wider spacing means that the breakdown voltage of the air insulator between the plates is increased. But wider spacing also reduces capacitance, so the plates tend to be larger and more numerous than in smaller capacitors of the same value.

Perhaps the ultimate in transmitting variables is the vacuum capacitor shown

Photo C. Transmitting air variable capacitor.

in Photo D. Although vacuum variables tend to be quite high-priced, I bought this 10-1,000 pF unit from Fair Radio Sales (see Table 1) for less than \$40 a couple of years ago. This particular capacitor is fitted with a small DC motor and a reversing relay. The capacitor is tuned by operating the motor, although it appears that removing the motor apparatus would make it possible to directly tune the capacitor.

Calculating the Tank Circuit Component Values

When we design an RF LC tank circuit it is usually for a specified band of frequencies. For example: 3,500 to 4,000 kHz for the 75/80 meter band (we actually want to tune a small overlap, so 3,490 to 4,010 kHz is what we'll use). We need to know what values of inductor and trimmer capacitor to use with specified main tuning capacitors. We first select a trial variable capacitor for the main tuning job. Look in a catalog for the minimum and maximum capacitances. For this example, I selected a Hammarlund MC-100-M from Ocean State Electronics (see Table 1) with a capacitance range of 7.7 to 100 pF. Refer to Figure 3 as you use this procedure:

Photo D. Vacuum variable (10-1000 pF) capacitor.

1. Determine minimum and maximum capacitance of C1 (7.7 - 100 pF).
2. Calculate ΔC : $C1_{\max} - C1_{\min} = 100 \text{ pF} - 7.7 \text{ pF} = 92.3 \text{ pF}$.
3. Determine the required frequency ratio (F.R.):

$$\text{F.R.} = \frac{F_{\max}}{F_{\min}} = \frac{4010 \text{ kHz}}{3490 \text{ kHz}} = 1.15$$

4. Calculate the required capacitance ratio (C.R.) by squaring the frequency ratio:
 $\text{C.R.} = (\text{F.R.})^2 = (1.15)^2 = 1.32$

5. Calculate the minimum total capacitance from:

$$C_{\min} = \frac{\Delta C}{\text{C.R.} - 1} = \frac{92.3 \text{ pF}}{1.32 - 1} = 288.4 \text{ pF}$$

6. Calculate the maximum total capacitance:

$$C_{\max} = C_{\min} + \Delta C = 288.4 \text{ pF} + 92.3 \text{ pF} = 380.7 \text{ pF}$$

7. Calculate the inductance by selecting either maximum or minimum capacitance, and the lowest or highest frequency (as indicated by the capacitance value selected). I selected the maximum capacitance (380.7 pF) and minimum frequency (3,490 kHz) combination:

$$L = \frac{10^6}{4\pi^2 F_{\min}^2 C_{\max}} \mu\text{H} = \frac{10^6}{(4\pi^2)(3,490,000\text{Hz})^2 (3.807 \times 10^{-10}\text{F})} = 5.46 \mu\text{H}$$

You can check the calculation with the normal resonance formula (below) to see if the correct frequencies are obtained at the minimum and maximum total capacitance (which correspond to the minimum and maximum values of C1 plus other capacitances in the circuit). The calculations should be accurate to within rounding errors (my calculator showed 3489+

and 4009+ kHz). The resonance equation is:

$$F = \frac{1}{2\pi \sqrt{LC}}$$

Where: F is in hertz, L is in henrys, and C is in farads.

In actual practice you will use a trimmer capacitor (C2 in Figure 3), and possibly a fixed capacitance (C3), to make up the difference between the required capacitance and the values obtained from C1. For example, we need a minimum capacitance of 288.4 pF, but C1 has a minimum of 7.7 pF. Thus, we need a total of 288.4-7.7, or 280.7 pF. The

trimmer should have enough range to account for any tolerance errors in calculation and the values of the parts. I selected a trimmer with a range of 8 to 100 pF, with the idea of setting it approximately in the middle of the range (or about 46 pF \pm a little bit). Thus far, of our required 280.7 pF, we've accounted for 7.7 + 46 pF, or 53.7 pF. We need to find an additional 227 pF. By using a 220 pF fixed capacitor at C3, we leave 7 pF for strays. In some RF circuits this is a reasonable value for strays, and the range of C2 (the "little bit" part) can make up for errors. In some Colpitts and Clapp oscillators, however, there is a tremendous capacitance contributed by the capacitive voltage divider feedback network, so these calculations are wrong for that case.

Sources of supply for variable capacitors include hamfests (but look out for the "sharks" who have inflated ideas of their capacitor's worth—"a crudded up transmitting variable is not worth anywhere near the high price commanded by a shiny new one . . . at least to me"). Table 1 lists some of the places where I've bought variable capacitors in the recent past. The listing for Maplins in England can be used for Americans . . . they accept Visa and Mastercard. The bank card companies will convert the price from £ to \$. Be a little careful reading the Maplin catalog, by the way . . . cost more than \$ (\$1.52/£ as of this writing), so the actual price is higher than it appears in the listing.

In Memorium

**JA1MP
SAKO HASEGAWA**

March 10, 1929 to June 12, 1993

Founder, Chairman of the Board

Yaesu Musen Co., Ltd.

Tokyo, Japan

As an electronic engineer and amateur radio experimenter, Mr. Hasegawa introduced Single Sideband Radio telephony to amateur bands in Japan in 1956. He constructed SSB generators based on the works of his contemporaries in the U.S., and soon had many requests for complete transmitters and receivers. In 1959 he incorporated Yaesu Musen Co., Ltd. to meet the demand for this equipment. From his inspiration and under his guidance, the company developed the FT-101 transceiver which revolutionized amateur radio. His spirit of innovation and engineering excellence continued with the development of Yaesu's flagship transceiver, FT-1000, that has set a standard by which other top flight transceivers are compared. Mr. Hasegawa was known throughout the company as a hands-on president, taking personal interest not only in the lives and work of each of his employees, but in everyone who chose to use Yaesu equipment.

His call sign, JA1MP became well known in many countries. He was awarded the first Japanese RTTY WAC award in 1971, and remained active in amateur radio and associated activities throughout his life. During the 1980's he co-founded and served as president of the Japan Amateur Industry Association.

As a testimony to Mr. Hasegawa's pioneering spirit and interest in technological advancement, Yaesu has become a leading manufacturer of radio communications equipment throughout the world.

ARSENE Is Up!

A new satellite has joined the growing assembly of active amateur-radio spacecraft. In a spectacular night launch from Kourou, French Guiana, ARSENE and ASTRA 1C were sent to orbit on May 11th riding an Ariane 4 rocket. While the launch went well, the new ARSENE hamsat has had difficulties with the VHF, 2 meter transmitter. Fortunately the satellite also has a SHF, 13cm transmitter and has been available for ham activity since early June.

The Long Road to Orbit

ARSENE is an acronym for Ariane Radio-amateurs Satellite ENseignement Espace. The program began 15 years ago through the efforts of three groups in France: RACE (Radio Amateur Club de l'Espace), ENSAE (l'Aeronautique et de l'Espace), and CNES (National Center for the Study of Space).

Many technical schools, universities and companies joined the partnership to get ARSENE in orbit. The design and construction of the spacecraft involved over 300 students and donations of time, money and components to build the satellite and prepare a ground station for spacecraft control.

The primary goal of the ARSENE program is to provide a satellite for amateur radio operators to use for experimental communications. The program is also devised to contribute to educational programs for satellite design and

telemetry studies. When launch day finally arrived, thousands of individuals had a stake in the mission.

The Launch Campaign

The rocket used to send ARSENE to space was provided by Arianespace and marked the 56th Ariane launch vehicle. The launcher was first prepared for flight in December 1992 to carry a Hughes communications satellite. The Ariane 4 rocket was configured with two solid-rocket, strap-on boosters. The launch was canceled due to technical concerns by Hughes. The rocket was moved back to the preparation area and re-configured for two strap-on, liquid-fueled boosters (42L configuration).

The Ariane launcher stands over 55 meters and weighs 362 metric tons at liftoff. It is a three-stage rocket using exotic fuel, asymmetrical dimethyl hydrazine with nitrogen tetroxide, in the lower two stages and liquid hydrogen and oxygen in the third stage. This configuration was designed to take nearly 3,000 kg of payload to a geostationary transfer orbit (GTO) with an apogee, or high point, of 36,000 km and a perigee, or low point, of 200 km.

The countdown on May 11th proceeded smoothly. Launch was nominal and all systems performed well. Both payloads were delivered to GTO and released to the customers; BETZDORF of Luxembourg for ASTRA 1C and RACE for ARSENE.

The Payloads

The main payload for flight V-56 was ASTRA 1C. It is the third spacecraft in

Photo A. The Ariane 42L launch vehicle with two strap-on liquid boosters in preparation for launch from Kourou, French Guiana, May 11, 1993. (Arianespace photo.)

the direct-to-home European TV satellite fleet. ASTRA 1C weighs 2790 kg. and can carry 34 TV channels through 18 transponders. Stabilization is three-axis and available power is 3300 watts from the solar panels at the end of the satellite's estimated 15-year life.

By comparison, ARSENE is very small at only 154 kg. The craft is spin-stabilized, has an estimated lifetime of three years with an estimated end-of-life power of 42 watts provided by a sheath of gallium-arsenide solar cells. Compared to most hamsats however, ARSENE is large, complex and powerful. It was designed to carry a Mode "B" digital communications system using standard AX.25 packet on three separate 70-cm uplinks to a single two-meter downlink. A second transponder was designed for linear operation using Mode "F" (like Mode "S" on AMSAT-OSCAR-13, but with a downlink 46 MHz higher). The uplink is 16 kHz wide and centered on 435.100 MHz with a downlink centered

on 2446.540 MHz. High-speed CW telemetry is sent on 2446.470 MHz.

The Problem

An amateur radio monitoring station on Reunion Island in the Indian Ocean off the east coast of Africa was the first to be in range of ARSENE after release to GTO. The 2 meter downlink signal on 145.975 MHz was expected but not heard. A second Reunion station also reported no signal.

Fortunately the S-band transmitter was working and the ARSENE control station FF1STA in France could receive telemetry on their 7 meter dish. Preparations were made to fire the onboard booster rocket to raise the dangerously low perigee to the desired height of 20,000 km.

Several theories have been suggested concerning the silence of the 2 meter transmitter. The most probable cause is a break in the cable from the transmitter to the antenna or perhaps serious antenna damage. Signals have been detected on the 2 meter downlink, but are so weak that only serious moonbounce stations have reported reception. The designers and builders in France will continue searching for explanations and possible cures.

It's Time for S-Band

Rather than mourn the loss of ARSENE's two-meter transmitter, many stations have begun modifying and upgrading their home stations to work with the new satellite on Mode "F." Any station capable of 500 to 1000 watts EIRP on 435.100 MHz can hit the uplink. A 50-watt transmitter to a 10-dB gain antenna will work. For the downlink on 13cm more effort is required. While A-O-13's S-band transponder can be heard on a two-foot dish with appropriate preamps and converters, ARSENE cannot. The signals are nearly 10 dB down from A-O-

13 levels. This means that a six-foot dish is needed, or some other array with similar gain. The downlink frequency may require some modifications to existing S-band receive converters due to the 46 MHz difference with A-O-13's downlink.

Articles in recent issues of the AM-SAT Journal by Ed Krome KA9LNV and James Miller G3RUH show some ideas on S-band gear for A-O-13 and ARSENE. Ed also wrote "Elementary Mode S" in the March 1991 issue of 73 describing some of his efforts to get results without pain at 2400 MHz.

Companies that provide receive converters and preamps include Down East Microwave (Bill Olson W3HQT) at (207) 948-3741 and SSB Electronics (Jerry Rodski K3MKZ) at (717) 868-5643. For ARSENE reception, adapted six-foot or

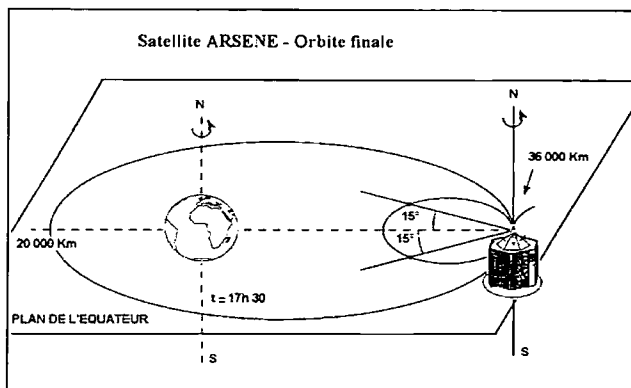

Figure 2. Sequence of events following separation from the Ariane launcher from the geostationary transfer orbit to the final orbit.

Photo E. View of the ARSENE internal booster for final orbit insertion.

larger TVRO dishes can provide the needed gain when used with a small helix antenna at the dish focal point.

Most of the pictures and figures shown were down loaded from Kitsat-OSCAR-23 at 9600 bps in .GIF image format. Further details on the satellite and its telemetry can be found in the March 1993 "Hamsats" column. AR-

SENE represents a real challenge for satellite enthusiasts. The DX opportunities from its high elliptical orbit are excellent and well worth the effort to configure a station for S-band reception. When Phase 3-D (the next high-orbit satellite) is launched a few years from now, the S-band system promises to be one of the most popular modes.

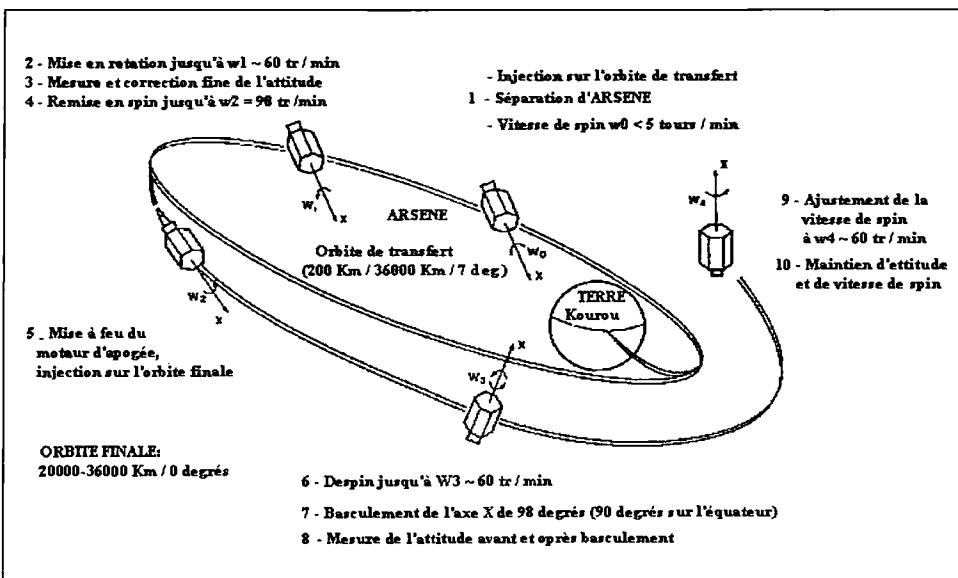

Figure 3. The "Orbite finale," or final orbit, planned for ARSENE is very different from all previous hamsats.

Computer Control for Beam Antennas, Part 1

Give your station a smart, new twist.

by Ron Cole K4OND

If you are an experimenter, you have almost certainly seen bargain TV antenna rotators at hamfests and speculated about using them for ham antennas. You may have hesitated at buying an untested rotator even at five bucks. Hesitate and speculate no more! Those rotators work very well for lightweight VHF/UHF antennas, and can be easily fixed (in most cases). Furthermore, you don't even need to have the indoor control box to make them work. Even if you already own or plan to buy a heavy-duty rotator intended for ham use, most of the principles in this article still apply, and may save you some bucks on repairs when those units fail. This article will also show you how to do automated pointing and/or tracking, including how to control the antenna via a joystick. Although it is aimed primarily at the use of TV antenna rotators and UHF antennas for satellite communications, this article will also teach you a lot about how to take full control of other rotators. In Part I we will look at how typical rotators work, how to control them electrically, and how to read out the azimuth and/or elevation. In Part II we will extend the concepts to computer interfacing, automated pointing, and joystick control.

Rotator Basics

The rotator motor itself is a surprisingly small device, running at about 3600 rpm, and geared down to produce the final antenna speed of about 1 rpm or less. The motor power, supplied through the control cable, is usually about 40 VAC derived from a transformer in the control unit. There are actually three power connections to the motor. One of these is connected to one side of the 40 VAC winding; the other two control the direction of rotation. One of the big mysteries of rotators, direction control, is actually very simple (see Figure 1). A relatively large unpolarized capacitor (C1) is used to produce a phase shift between the other two motor power connections, and it is this phase shift which controls the direction of rotation. Thus, controlling direction only requires a switching of one side of the 40 VAC winding to one side or the other of the phase-shift capacitor. This is done inside the control unit as a part of the direction dial function. By the way, these capacitors are a high-failure-rate item: Almost every "bad rotator" I have found turned out to have a bad phase-shift capacitor. Fortunately, you can easily get a replacement at most appliance repair and electrical supply stores; they are known as "motor-run" capac-

itors. They come in a wide range of values and are rated at voltages well above the 40 VAC used in this application. All you have to do is find an approximate match to the one in your control unit; I have capacitors as much as 50% higher in value than the original one without any problems. Before I learned about motor-run capacitors I tried back-to-back electrolytics and those apparently will not work. While this experience is only based on TV rotators, it almost certainly applies to other rotators as well. It's the first place to look when your rotator won't rotate!

It's not enough to just control the direction of rotation, of course. You also need to get feedback on position (i.e., azimuth), and to stop the rotation when the desired position is reached. In most TV rotator controllers the position feedback is produced by an electromechanical coupling, driven by a solenoid. Refer again to Figure 1. Within the rotator housing, and as a part of the step-down gearing, a rotating cam is used to close the contacts of a switch. The cam is higher up in the gear train and rotates much faster than the antenna. It can produce switch closures for about every five degrees of antenna rotation (depending on the exact model). Each switch closure results in activating a

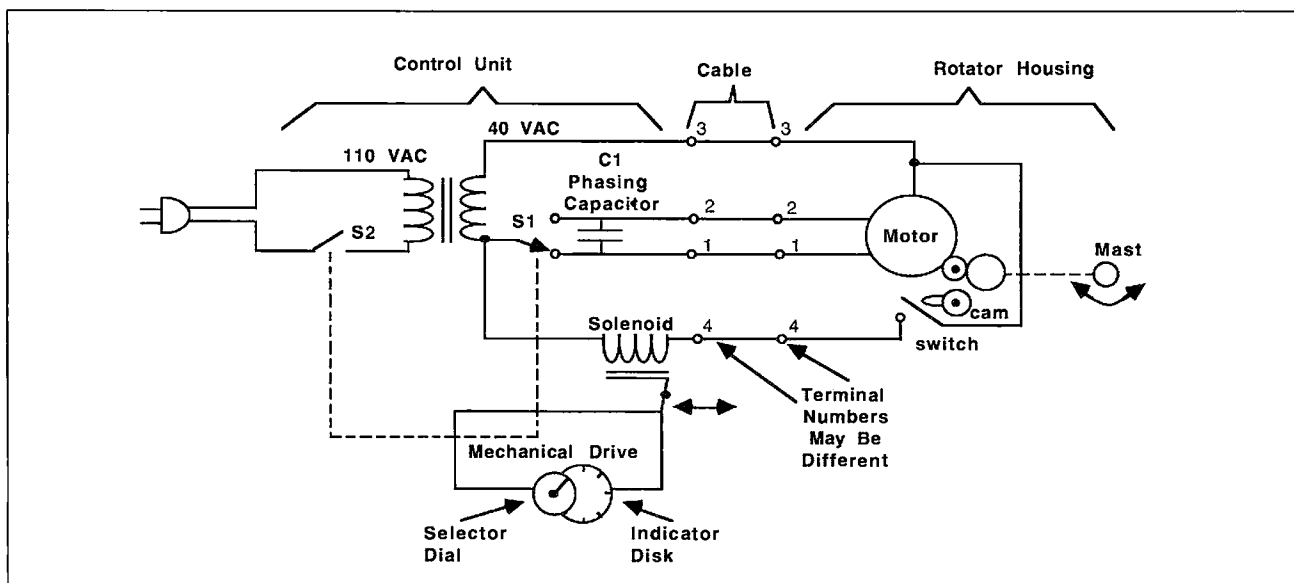

Figure 1. Typical rotator and control box.

solenoid in the control unit, and a mechanism connected to the solenoid turns the position indicator. (It is the firing of that solenoid which produces the typical "clack . . . clack . . ." sound when the rotator is turning.) A very messy set of mechanical and electrical components is used to cause the indication wheel to turn in the right direction, and to stop when the position indicator wheel is aligned with the direction dialed in by the user.

Another, and less common, type of position readout scheme involves using a second motor inside the control unit itself, and running exactly in parallel with the motor in the rotator on the mast. This second motor has a similar step-down gear train, but all it does is drive the position indicator wheel. Again, a mechanical or electrical scheme is used to detect when the two dials match, and stop the rotator. You can easily distinguish between these two types of rotator and control units. The first type (with a switch in the rotator) requires a four-wire control cable (three for the motor, one for the switch); the second type needs only three wires in the control cable.

Both of these types of position indicators are noisy and not easily adapted for any type of position readout other than the mechanical indicator dial. I have also found a few failures in the mechanisms which are virtually impossible to repair. Fortunately, we will soon see how the whole control box can be thrown away (except the 40 VAC power transformer and phase-shift capacitor).

There is one other feature of TV rotators which is important if your intended use is in a satellite antenna elevation system. This feature is the method for attaching the mast to the rotator. For easy adaptation to elevation use, you need to find a rotator which allows the mast to pass completely through the housing (see Photo A). You may have to do some searching to find one of these; they seem to be of older manufacture. All of the new rotators I have seen on the market are built so that the end of the mast rests on the

Photo A. K4OND's remote-controlled rotating 2-meter yagi and 70 cm heil antennas.

rotator housing itself, or on a plate which is a molded part of the housing. If the latter type is the only one you can find, it may be possible to carefully cut the plate off and allow the mast to extend beyond the housing in both directions. This approach is necessary since the elevation rotator will normally be mounted at the top of the vertical mast, with a horizontal boom extending out both directions for the antennas themselves. (You may also want to use this type for an azimuth rotator, for the reason discussed below on using potentiometers for position readout.)

Now let's put together a better manual system, and one which is readily adapted to computer control.

A New Control System

It is trivially simple to construct a system to control motor direction and starting/stopping rotation. All it takes is the 40 VAC transformer, a good capacitor, and a center-off toggle switch (a good one is the Radio Shack #275-710, which is spring-loaded for the center-off position). See Figure 2. When you hook up the power wires to the rotator

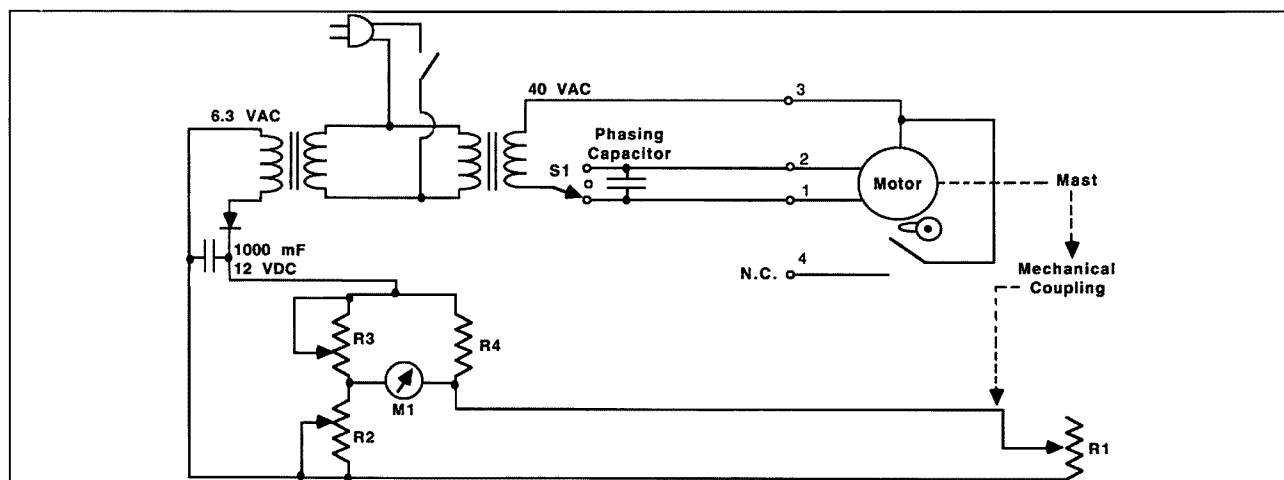

Figure 2. Simple "manual" controller and display. S1 is a center-off toggle. R1 and R2 should be equal, approximately 10k; R3 and R4 should be equal, approximately 5k. M1 should be 0-1 mA, up to 0-10 mA. If a less sensitive meter is used, decrease R1-R4. Adjust R2 and R3 for zero and full scale as R1 varies over its range. Duplicate the circuit if a second rotator is used.

motor, the only one which is critical is the lead which goes directly to one side of the 40 VAC transformer. The other two leads are completely interchangeable. The critical lead is usually marked "3" on the terminal strip on the rotator housing. If all else fails, just try different combinations until you find the right one; the motor will not be damaged by brief periods of wrong connections, it just won't run. The next part gets a lot more involved: how to get feedback on antenna position, and how to display it in an attractive way.

Analog Position Readout Concepts

These "analog" schemes involve mechanically coupling a potentiometer to the mast or boom. With the potentiometer turning in synchronism with the mast (or boom), you can use a meter to read voltage (or current) through the potentiometer, and calibrate the meter in terms of position. We have to find a way to accomplish this mechanical coupling. One of the problems you will find in the case of the azimuth rotator is that ordinary potentiometer shafts don't turn a full 360 degrees like the mast, so you will have to step the rotation down with different sized gears or belt pulleys, or go to a 10-turn potentiometer. I did find a set of gears which could fit into the rotator housing, in place of the cam which normally operates the solenoid-control switch. I brought the shaft out through a hole drilled in the housing and coupled it to a 10-turn potentiometer, but finding these parts was more pure dumb luck than anything else. It is certainly possible to use a rubber drive belt (such as can be found in VCR repair shops) passing around the mast and over a pulley attached to the potentiometer shaft, or maybe even a fairly large "rubber tire" wheel on the potentiometer shaft, mounting it so that the "tire" bears directly on the rotating mast.

A better scheme would be to find a fine-toothed gear which is a little larger than the mast; take the gear and a short section of mast to a machine shop and get them to cut a mast-sized hole through the center of the gear, and braze the gear onto the mast section. Simply insert the short mast section into the rotator, and add more mast sections as needed. Then, mount the potentiometer, with a matching gear, on the fixed portion of the rotator housing so that the gears mesh. Finally, if you can find one of the rotators which allow the mast to pass completely through the rotator, you can put a wooden plug into the very bottom end of the mast, drill a hole slightly less than 1/4" in the center of the plug, and force-fit a shaft into the plug. Then you can couple the pot to the shaft (through a step-down gear, or use a 10-turn pot). Obviously, some mechanical ingenuity is required in any of these methods.

For the elevation rotator, there is a simple scheme which works very well. This scheme involves attaching a potentiometer to the horizontal boom, with the shaft of the pot in line with the boom, then hanging a weight on the potentiometer shaft. As the boom rotates

Photo B. The azimuth rotator is mounted between the rafters and the ceiling joists.

up and down, the weight turns the potentiometer shaft, producing the desired change of resistance. Since the elevation will normally be a maximum of 90 degrees (i.e., from horizontal to straight up), we don't even have to worry about exceeding the potentiometer shaft rotation limits. In my elevation system, I simply fastened a large coffee can to the underside of the boom, and mounted the potentiometer and weight inside the can for protection from weather and wind effects. This scheme, while very simple and effective, does have one drawback: As the boom is turning, the weight has a tendency to swing slightly, causing the meter needle to oscillate as well.

As shown in Figure 2, each sensor potentiometer is connected as one arm of a bridge circuit, with the 0-1 mA meter as the position indicator. Typical values for the bridge components are as listed in the figure, but many others will work, and you will probably have to do some "trial and error engineering" anyway to get the meter to deflect full scale as the sensor pot moves. Do this on the bench, before you mount the pots on the rotators!

Although it is possible to use other devices including rotary switches, or even to electronically count the closures of the solenoid control switch, using potentiometers for position sensors has a real advantage if you intend to go all the way to a computer-controlled system: You can read the potentiometers through "joystick" ports, and use software to convert the reading to an antenna

position. (We will explore the concept in Part II of this article.)

Mechanical Assembly

Although this article is mostly about controlling rotators, a few words about rotator mounting may be of help when you build your system. If you used an azimuth rotator which allows the rotating mast to pass completely through the rotator housing, you can save some strain on the rotator by mounting it near the bottom of the mast and placing a bearing of some type under the mast bottom. In one such installation, I poured a small block of concrete in the ground, and stuck a three-foot section of mast near the center. The fixed portion of the rotator mounts on that short section. The rotating mast passes through the rotator, with the base of the mast resting on a ball-bearing mount salvaged from a heavy-duty caster assembly with the wheel removed. The bearing "bears" most of the weight of the mast. The concrete block is about a foot away from the wall of the shack; just below the eaves of the shack a support arm extends from the wall, fitting around the rotating mast just tight enough to provide support without clamping the rotation.

Another method, which worked very well, was to cut a hole in the roof of the shack for the mast (and using a rubber vent-pipe boot to prevent leaks). The azimuth rotator mounts on a vertical board between the rafters and the ceiling joists, and the mast rests on a bearing on a platform on top of the joists. (See Photo B.) The rotating mast protrudes through the roof only about six feet, but absolute height is not that significant when the satellites are more than a few degrees above the horizon. In both cases, the elevation rotator is mounted on an aluminum plate (an old rack panel) mounted to the vertical mast with U-bolts. Holes are drilled in the plate to accept the bolts on the elevation rotator which originally clamped the rotator to a vertical mast. You may be able to make out enough details in Photo A to see this scheme, as well as the 2 meter yagi and 70cm helix in my system, and the coffee can which holds the elevation potentiometer and weight. The two antennas are placed so as to balance the weight on the boom, including the counterweight protruding from the rear of the helix. Close attention to balance will go a long way towards preserving the life expectancy of the rotators.

That's it for Part I. We have seen how to control rotators, how to fix the most common problems with non-working rotators, how to get rid of the electromechanical control unit, and how to get electrical position readouts which are much easier to see than the dial on the original control unit. Is it worth the trouble? Maybe not if you only want to have manual control of your antenna position, but if you want to do computerized control and automatic positioning/tracking, the conversions described above are essential. In Part II we will expand the system to one which provides both manual and computer control, and even allows for the use of a joystick as the control device.

More Internet Options

I think columns on Internet connectivity get more response than any other subject. I have had many requests for some TCP/IP info—these haven't been ignored. I am working up to a TCP/IP series, so stand by. In the meantime, here's some information for you Internet junkies out there that I think you will find fascinating.

What is the Internet, Anyway?

For the uninitiated among you, here's the scoop. The Internet—note the big "I"—is an enormous network of computers of every description. These computers are located in educational institutions, military installations, commercial enterprises, even hamshacks. These machines—in one way or another—are all connected together using TCP/IP (Transport Control Protocol/Internet Protocol).

TCP/IP—often just called "IP"—was developed by DARPA, a Defense Department wing—to make the Internet possible. The idea of the Internet is something similar to the Interstate system. The federal government built the Interstate system citing national security issues. How could Washington be expected to defend California without a road to get there? While the need for the Internet was not quite as clear-cut, some way was needed for the educational, military, and research organizations who worked together on defense department projects to share data.

Today, the infrastructure of the Internet is maintained by private, regional companies who sell connections and maintain the complicated "routers" needed to insure that your messages get to their destinations.

How About Ham Radio?

Hams get involved in at least a couple of ways. First, quite possibly the most common implementation of TCP/IP protocol for the PC was written by a ham—Phil Kams—and bears his call as a name, KA9Q. The Internet uses Ethernet—a networking scheme developed by Xerox at PARC (their Palo Alto Research Center). Ethernet connections require special hardware, a board called an NIC (Network Interface Card). Each card has its own special "driver" software that understands its hardware and allows oth-

er software to communicate through it. With KA9Q, these drivers are called "Packet Drivers" (no direct relationship to packet radio) and are available in the public domain—making them very popular.

Because these drivers are interchangeable—new hardware, just get a new driver—it is possible to create one for use with an amateur TNC (Terminal Node Controller) running in KISS (Keep it Simple, Stupid) mode. This means that the KA9Q software can be used to run TCP/IP protocol over the air using nearly any modern TNC. This is the heart of TCP/IP amateur operation.

cessible only to licensed hams. To do this, they came up with the idea of "encapsulation." This bit of Internet magic is a little hard to understand. The basic idea is to wrap a TCP/IP frame (data packet) inside another one—encapsulating it. This successfully hides the true origin and destination of the frame, and makes it possible to control which ones will get through to the radios. The term "wormhole" was adopted for this technique, which is very successfully used today.

Wormholes now connect hams in places like Australia, Hawaii, California, Indiana, and even countries in Europe. Practically speaking, this means that I can take a look at a BBS in Melbourne, Australia, from my home in southern Indiana, using a 5 watt handheld. Fun, fun, fun!

Getting Involved

As I said in the introduction, I

***"For the uninitiated among you,
here's the scoop. The
Internet—note the big 'I'—
is an enormous network of
computers of every description."***

Ham stations running TCP/IP offer some interesting possibilities. One really big one, not lost for a moment on the hams involved, is the use of the Internet to send data anywhere—or nearly anywhere.

The only problem these hams had—other than malfunctioning keyboards, brought on by the drooling anticipation of actually making this connection—was to insure that FCC regulations were not violated. They had to be sure that access to radio transmitters located at the end of these Internet links were ac-

cessible only to licensed hams. To do this, they came up with the idea of "encapsulation." This bit of Internet magic is a little hard to understand. The basic idea is to wrap a TCP/IP frame (data packet) inside another one—encapsulating it. This successfully hides the true origin and destination of the frame, and makes it possible to control which ones will get through to the radios. The term "wormhole" was adopted for this technique, which is very successfully used today.

First, from the radio side. Thanks to the growing popularity of IP as a way of networking PBBSs (Packet Bulletin Boards Systems), the idea of AX ↔ IP gateways is catching on. With these systems, the packet user connects to the PBBS using ordinary AX.25 (packet) protocol, and the PBBS provides access to the Internet functions through a

menu. This is lots of fun.

The WG7J PBBS software seems to be the most popular, so I'll discuss it. First of all, the PBBS will allow the exchange of packet messages just like any PBBS. There is a difference in presentation, though. With a WG7J system, messages are collected into areas, and the area command (abbreviated "a") allows the user to switch among them. The areas are based on topics, like SALE, BARTER, WX, etc. There is also an area created for each user—any messages to you will appear in an area named with your call. This is a much more convenient system to use than the more familiar WØRLI type listing.

Many of the other commands will be familiar or self-explanatory. I will ignore those and concentrate on two Internet options, "finger" and "telnet."

Finger

The Internet utility finger is used to query a remote system for information. It has two basic purposes in the Internet world, one is to get information about users and systems—the other to get specific text files offered by systems for the convenience of users.

The first use allows a user to determine if a particular person is a user of, or is known by, a machine. The syntax is simple:

finger N1EWO
would tell you whatever the system you are currently using knows about me.

finger N1EWO@K9IU.AMPR.ORG

would tell you what the PBBS run by the folks at Indiana University in Bloomington knows about me.

The other use is also simple. What you can do with it depends on what the sysop at the system you are fingering wants to offer. For example:

finger weather@iugate
will return the NWS forecast for central Indiana. This is one of the ways in which Internet resources are available.

Telnet

The telnet utility is very powerful, if very simple. Basically, it allows you to connect, as a user, to any system willing to have you. For example:

telnet n8imo.ampr.org
will connect me to N8IMO's WG7J PBBS in Michigan. When you telnet you will generally be logging into a UNIX system (or something acting like a UNIX system). You will be presented with a prompt:

login:
Use your callsign, then when prompted for a password, try "amateur" (omit the quotes). There are two things to keep in mind. First, UNIX logins accept just about every

?A,B,C,D,E,F,H,I,J,IP,J,K,L,M,N,NR,O,P,R,S,T,U,V,W,X,Z # h					
Usage					
H[elp] [<command-name>]					
Description					
The help command will display help for a given command. The help command by itself, displays this particular message. To get help for a specific command, enter "help" followed by a space and then the name of the command you want described. The following commands have help descriptions available for them:					
area	bye	connect	download	escape	finger
help	info	jheard	kill	list	musers
nodes	operator	ports	read	send	telnet
upload	verbose	xpert	what	zap	
Examples					
help area (displays a description of the "area" command)					
h download (displays info about downloading files)					

Figure 1. "The help command output for a WG7J system. Note the unusual commands like "finger" and "telnet" used for Internet connections—see the text for more."

character your keyboard can generate as part of the user name and password. If you mistype, a backspace may not clear up the problem. The second thing is that UNIX is case sensitive—that is, it cares about the shift key. Type the call and password in all lowercase. If you do not, the system may not let you in, or it may decide that you want everything in UPPER CASE FOR THE REST OF YOUR SESSION. This can be very annoying.

Other resources available via telnet are various sorts of "servers." These machines offer information of all sorts which can be very useful. For example:

telnet 141.212.196.79 3000

will connect you to the University of Michigan's "Weather Underground." This is a weather server that provides nearly every text product produced by the National Weather Service, including forecasts and severe weather bulletins. This is a marvelous resource for you "Sky Warn" participants out there.

Coming in the Other Way

I told you I'd have some exciting news for Internet junkies! Those of you with landline Internet access can get involved from the other direction. If you have access to Inter-

net telnet, try:

telnet K9IU.UCS.INDIANA.EDU

Login with your callsign and the word "amateur" for a password. The first time you log in, you won't be able to do much except leave a message to the sysop (s sysop). Leave a message requesting access, along with the password that you want to use. In a few days, you'll have an account—and "amateur" will no longer work as a password. Once you have access you will be able to telnet onto the amateur IP network and have lots of fun.

There is a lot more to the Internet and ham radio than what you have read here. I hope you choose to explore it. Keep your eye on this column for more information.

A Request of Sysops

If you are a sysop of an AX <—> IP gateway, I would love to hear from you so I can let people know that you exist. Send mail to:

jsloman@bix.com

with your PBBS info, including your frequency and intended coverage area.

73 de N1EWO.

OAK HILLS RESEARCH QRP Headquarters

QRP WATTMETER KIT

- A wattmeter designed specifically for the QRP operator & builder
- Measures forward & reflected power at QRP levels
- Select from three full scale power levels: 10W, 1W, or 100mW
- Measure power down to 1mW
- Large easy to read 2" meter
- Low current drain meter circuit uses 9V battery (battery not included)
- Great for portable use
- Easy to build & align
- Align with a digital voltmeter. Source of RF not required
- Measures (HWD): 4 1/2" x 3 1/2" x 5"
- 100% complete kit (less battery) including cabinet, all components and instructions

The ears have it!

When we introduced the American-made R8 Worldband Communications Receiver, we knew it would be judged by some very discerning ears, experts accustomed to the finest in short-wave listening equipment from around the world. After listening to the world on the Drake R8 loud and clear, they have delivered a decisive verdict.

They appreciated the R8's sensitivity, clarity, simplicity, and all-around versatility so much that many of them declared the R8 simply the best of its class. High praise, indeed, from very well-traveled ears.

But why take the word of mere

“The R8 is like a breath of fresh air, with its ground-up engineering and up-to-date digital control from the front panel. I am very pleased to see a quality HF receiver of American manufacture that should successfully compete on the world market.”

Bill Clarke

73 Amateur Radio Today

experts? Put the Drake R8 to the test yourself with a 15-day money-back trial period on factory direct purchases, and let your ears be the judge. If you're not impressed by Drake's quality, performance and ease of operation, all in a receiver costing less than \$1,000.00, return the R8

Receiver within 15 days, and we'll refund your money in full, less our original shipping charge. To order your R8 factory direct, for more information, or for the dealer nearest you, call **1-800-723-4639** today. We're confident that once you've listened to the R8, your ears will hear of nothing else.

chance of rendering the chassis of your teleprinter hot, creating a potentially lethal situation.

A line isolation transformer simply isolates you from that situation, without changing the voltage. Connecting the secondaries of two filament transformers to each other, as shown in Figure 2, accomplishes just that goal, at minimal cost.

As for the loop supply itself, it can be as simple or complex as you would like it. Figure 3 is my favorite basic supply. Just a transformer, a diode, and a capacitor are all you need to get basic direct current. The current limiting resistor is needed because of the low resistance of the selector magnets. In the typical Model 15 teleprinter, there are two selector magnets, each with a resistance of 105 ohms. Accessible on terminals 45 and 46 on the side of the machine, they may be connected in either series or parallel. A series circuit, with a total resistance of 210 ohms, is designed for operation at 20 mA, and a parallel circuit, with a combined resistance of about 52 ohms (according to Bob's memory), is for the more common 60 mA loop. Now, if the loop supply delivers 150 volts, and the resistance of the magnets is about 52 ohms, the resultant current would be (remember Ohm's law?) $150/52$, about 3 amps! "Burn out those magnets real quick, don't 'cha think?" Therefore, a series resistor is included to limit the current to

the proper 60 mA current. Normally, this is about 2000 to 2500 ohms. It is important to make this a high powered resistor, though, as, for example, with our 150 volts at 60 mA, the wattage will be 150×0.06 , about 9 watts.

So there you have it, a simple driver for older machines to let you run a teleprinter off a low level signal. Hope this is useful to you, and I look forward to receiving other thoughts on this ever-changing subject.

Collect the Whole Set!

Speaking of changing, the latest disk of software is filling up, with more RTTY goodies. Any of the four of the collection can be yours. Just send either a 5.25" or 3.5" disk, \$2 per disk to be filled, and a note telling me which collection you want, along with a self-addressed, stamped disk mailer, and I'll get it back to you right away. Collections #1, #2, and #4 are RTTY/packet programs; collection #3 is a bunch of archiving and viewing utilities. Just send me a self-addressed stamped envelope if you want a list of what's in each archive collection, if you want to peek first.

I look forward to more mail and comments this month. The summer is here and we can all feel energetic. Drop me a note at the above address, or Email via CompuServe (ppn 75036,2501), Delphi (username MarcWA3AJR) or America Online (screen name MarcWA3AJR). 73

AUTOMATIC SIMPLEX REPEATER

THE SR-7110 CONNECTS TO ANY TRANSCEIVER TO MAKE A SIMPLEX REPEATER

- Portable or mobile repeater to increase the range of HTs
- Emergency repeater
- Test repeater to hear your own signal
- Test for skip conditions
- Unmanned hidden transmitter
- Calling frequency machine

The 7110 has two modes of operation. In the automatic mode the repeater only repeats when there is no reply to a transmission within two seconds. In the continuous mode all transmissions are repeated without delay. The 7110PL has a PL decoder so the frequency can be used without the repeater.

SR-7110 \$200.00

SR-7110PL \$275.00

Radio Direction Finding

Joe Moell P.E. KØOV
P.O. Box 2508
Fullerton CA 92633

For T-Hunters Only . . . Not!

As you leaf through ham magazines, you won't find ads for lots of products designed specifically for transmitter hunters. Nevertheless, radio direction finding (RDF) enthusiasts can find many items that are useful on "foxhunts" or "T-hunts", as RDF contests are called.

Often, the sellers of these products don't mention their foxhunting applications. I suspect that's because they are unaware of them! This month, we will look at three offerings that are aimed at the mainstream ham radio market, but are of special interest to T-hunters.

World's Lightest Yagi?

Hiking and emergency preparedness, as well as RDF, were on the minds of Mike Walker KAØVFF and Al Lowe NØIMW when they developed the Arrow Antenna (Photo A). This 4-element 2 meter yagi is rugged, yet very lightweight. It can be assembled and disassembled quickly. Elements fit into the aluminum boom or the supplied PVC pipe carrier for storage and transport.

T-hunters quickly recognized this beam's suitability for mobile RDF. They have been talking it up since construction plans were published in the April 1992 issue of *73 Amateur Radio Today*. For example, I recently communicated with hams in Montreal and Memphis who use arrow designs on their local hunts. Many RDFers have duplicated the

antenna from the magazine article, while others have purchased theirs ready-made from the Arrow Antenna company.

KAØVFF has stepped aside, leaving NØIMW as the sole proprietor of Arrow Antenna. Al and his family are churning out yagis and doing a brisk business at hamfests and via mail order. "I've been selling a lot of them to hams on the front range here in Colorado," he says. "Search and rescue is using them, and so are some balloon trackers."

Al and Mike cleverly picked lightweight aluminum arrow shafts for their beam elements. At about 1-1/4 pounds, the Arrow Antenna is much easier to turn at low vehicle speeds than my PVC-pipe stiff-wire T-hunt quad. I was surprised when I compared Arrow shafts to the usual hollow aluminum antenna tubing. An Arrow element of the same outside diameter and length weighs only half as much as a tubing element!

Masts and associated hardware are not supplied by Arrow Antenna. Al says a metal mast does not impair the beam pattern, but I used thick-walled PVC pipe for my mobile tests. I mounted a U-bolt permanently to the mast and drilled two pairs of holes in the boom at the center of gravity. This allowed me to change the yagi quickly between horizontal and vertical polarization without affecting my mast pointer alignment. Some T-hunters have designed 90-degree hinges for instant polarization change.

In my RDF tests, the Arrow Antenna had slightly higher gain than my regular 4-element quad. Its

front-to-side and front-to-back pattern was excellent. Good SWR was obtainable across the entire 2 meter band.

For close-in hunting on foot, Al suggests reconfiguring the antenna by removing the front director and swapping positions of the other director and reflector on the boom. This gives you a 3-element beam with a 15-inch mast handle in the rear for easy carrying.

Despite its light weight, this yagi withstands the rigors of mobile foxhunting well. Parts and workmanship of NØIMW's antennas are guaranteed for one year. Al says, "In my T-hunting experience with tree limbs and street signs, the only damage has been to bend the 8-32 studs that attach the elements. These can be easily straightened or replaced to finish the hunt." Replacement threaded rod is readily available around the country.

RF by the Numbers

A field strength meter (FSM) is a simple untuned receiver that visually indicates the relative strength of the surrounding RF field. Hams most frequently use FSMs to compare the gain and directivity of antennas, and to tune/adjust antenna matching networks.

T-hunters use FSMs for close-in RDF when the fox's signal overpowers sensitive portable receivers such as handie-talkies and scanners. Probing on foot with a FSM is called "sniffing."

Inexpensive unamplified FSMs require 50,000 microvolts or more of RF input for usable indications, making them unsuitable for sniffing except when the transmitter is inches away. Amplified sniffers have more sensitivity, but some have limited meter range or touchy zeroing adjustments.

I.C. Engineering has just introduced a DC-to-microwave FSM with

digital readout. The "I.C." in the company name isn't short for "integrated circuits." It stands for Ismael Charnabroda KD6TU, the company's owner. Ismael, a former aerospace engineer turned entrepreneur, is enthusiastic about his product.

The Digi-Field (Photo B) is a rugged plastic box 4-3/8" x 3-1/4" x 1-3/4" with an SO-239 antenna connector on top. An 18-1/4" telescoping whip antenna is also supplied.

The 1/2" high 3-1/2 digit liquid crystal display is ideal for antenna pattern checks. Set the unit on a fence or ladder several wavelengths away from the transmitting antenna under test and watch the readings on this FSM with binoculars as you tune and tweak the antenna or transmitter.

Battery life won't be a problem with the Digi-Field. It draws only 2 milliamperes, so its 9V alkaline battery will last hundreds of hours. An indicator tells you when the battery drops to 8V, but in my tests the accuracy was not affected until the voltage got down to below 4V.

With only one control (the on-off switch), operation of the Digi-Field is straightforward. KD6TU doesn't provide a detailed instruction manual, but he offers technical assistance by phone to buyers.

The original Digi-Field ("A" model) and its telescoping antenna will detect a 1-watt 2 meter handheld with "duckie" antenna at 65 feet. Overrange occurs at about two feet from the HT. The new "B" model is more sensitive, overranging at 25 feet.

Because the Digi-Field has an unshielded case, body capacitance affects readings. To avoid this, mount the unit to your sniffing antenna mast instead of holding it in your hands. Avoid touching the coax connector when sniffing, as the reading will be affected.

Photo A. The Arrow 2 Meter Yagi Model 144-4 has a suggested retail price of \$89.00 and is available from Arrow Antenna, 1461 Peacock Pl., Loveland CO 80537; (303) 663-5485. The latest model features caps on element ends for safety, instead of the sharp points shown here.

No sensitivity control is provided. You can shorten the antenna or add external attenuation to reduce the meter reading. However, the Digi-Field's internal wiring can pick up RF, so close-up measurements of powerful T's may not be possible, even with the whip antenna collapsed or removed. With the antenna disconnected, the 1 watt rig overranged the B model at 6 inches.

Digi-Field responds to RF from low frequencies well into the microwave spectrum. Full sensitivity is available to 1000 MHz, and reduced sensitivity continues to 12 GHz. While this is generally useful, it means that strong ambient RF fields can mask the signal you're looking for. You don't have to be at

a communications site to have high RF fields. When I held the B model over my head in the center of a large suburban park in Fullerton, California, the indication went to half scale, even though I was blocks away from the nearest transmitting antenna.

The detector output jack on the side of the Digi-Field can be hooked to an audio amplifier and speaker or phones to give you an idea of what is being received. Only amplitude modulation can be detected in this way; you cannot copy FM signals. The jack will not drive an earphone directly, and the wiring to your amplifier can cause additional unwanted signal pickup.

As with all FSMs, Digi-Field measurements are relative, not absolute. The digital readings are not in dBm, milliwatts, microvolts, or any other units. KD6TU will provide typical power-versus-readout graphs on request. You can perform your own crude calibrations with a laboratory signal generator, but your indications will vary with frequency, temperature, and source impedance. For foxhunt sniffing, all we care about is relative strength, so this is of little concern.

Lilliputian ID-8

Engineers at Communications Specialists weren't thinking of the RDF market when they designed the ID-8, a miniature CW identifier. But Mike Wolfe N9CHQ, who purchased one of the first units, was quick to see its T-hunt possibilities. He wrote to me on CompuServe that an ID-8 is the brains of a fox transmitter he built to put on hunts for the North Shore Radio Club in Highland Park, Illinois.

The ID-8 is a tiny circuit board (1-7/8" x 1-1/8") with a surface-mounted 6805 microprocessor, EEPROM, and voltage regulator. Hook it to a transmitter and it will generate CW identification at programmed intervals, either by keying the carrier or by providing a keyed sine wave tone to the modulator.

Photo C. The ID-8 identifier board and keypad has a suggested retail price of \$89.95 and is available from Communications Specialists, Inc., 426 Taft Ave., Orange CA 92665; (800) 854-0547; (714) 998-3021.

The ID-8 can send up to eight separate CW messages. The eight messages can be played successively to form one long message of up to 216 characters. Messages are entered with a supplied 12-button keypad (Photo C), which is plugged into the ID-8. With this keypad, you also instruct the ID-8 how fast to send the CW (1 to 99 WPM) and how often to send the message (continuously, by external command, or spaced up to the 10-minute FCC limit).

There are several other programmable parameters including tone frequency and dead-carrier delay time before the message. When programming is completed, parameter and message data is stored in the EEPROM. You can then remove the keypad until you need to change call sign or timing for another hunt.

The ID-8 needs only 6 milliamperes from a 6 to 20 volt DC source. A 9V transistor radio battery will power it for days. Comm-Spec says it's immune to thermal variations and RF fields. The operating temperature range is -30 to +65 degrees Celsius.

N9CHQ was quite pleased with the ID-8 as a fox controller. Though

it lacks the distinctive tone patterns of the foxboxes discussed previously in this column, it was just right for his club's on-foot beginners hunts. "What I like about the unit is that I can program the ID and timing in the field," he wrote. "Normally I use 25% duty cycle, 15 seconds on, 45 seconds off. I program in the ID and then adjust the code speed so that it lasts for 15 seconds including a short delay on keyup. I then set the off time."

"Once it is programmed," he adds, "I connect a 3-conductor cable to the transmitting HT. I turn on the unit and it runs by itself. The unit's timer appears to be very stable. During the hunts in which we have used it I have not noticed any drifting in the timing circuit. It really works beautifully, and does not need any shielding."

From my standpoint, the main appeal of the ID-8 is its size. An ID-8 and keyer this small seems perfect to go with the subminiature VHF transmitter described in the May 1993 "Homing In." KB6TTS and I are designing an FM modulator and interface to connect these two boards. With luck, we will have tested circuits for you next month.

Photo B. The Digi-Field Model A and B Field Strength Meters have a suggested retail price of \$119.95 and are available from I.C. Engineering, 16350 Ventura Blvd., Suite 125, Encino CA 91436; (818) 345-1692 (Tech. Info.), (800) 343-5358 (Orders).

Dayton '93 Youth Forum

It's always an auspicious occasion when grown-ups get together to honor the achievements of children. Certainly, the young adults who showcased their achievements at the '93 Dayton Hamvention Youth Forum deserved the spotlight. It was an honor to moderate a forum with such talented children from across the country.

Our first speaker was Rusty Smith KD4GLC, who is 17 years old and is an Assistant Section Manager in Kentucky for the ARRL. His main responsibility is to recruit young people into ham radio. Rusty is interested in DX-ing and contesting. He told us that his goal was to lead the state of Kentucky in the Novice Roundup using CW only. He succeeded, and said that this event was the most fun he has had so far as a ham radio operator.

Barry Kennedy N2PNG is 16 years old and comes from New Hampshire, where he attends the Dublin School. Barry is active in recruiting young people and has done some teaching at Crothched Mountain School. This is a rehabilitation facility that has had some extraordinary results with their young people through the use of amateur radio classes.

I would never run a youth forum without at least one member of the distaff side. Shauna Richards N7NGT is a bright, pretty 17-year-old young lady from Rock Springs, Wyoming. Shauna was the first teenage girl in Wyoming to earn a ham license. That was on 8/8/88. In 1990 she earned 1st and 3rd place at the district and state science fairs as a freshman in the senior engineering division. Her winning science project was on five modified 2 meter antennas that would function well even if trapped under a collapsed double-decker highway, such as the

one which fell in the 1989 San Francisco earthquake. Then, in 1991, she received the Hiram Percy Maxum Memorial Award.

Matthew d'Alessio KC6VIM is 15 years old and lives in San Anselmo, California. He captivated the audience with his eloquence and confident manner in front of such a large group. Matt spoke about how much he enjoys CW. He also enjoys working 2 meter FM with his hand-held radio. Matt says, "There is nothing like working the world on a few dots and dashes on a cold winter night. I have talked with hams in 60 countries using these 'crazy beeps.' Matthew got a terrific reaction from the young people in the audience.

Eric Permut KB0KQF is a 12-year-old from Boulder, Colorado. I first heard about Eric from Rip and Ellie Van Winkle, who run license classes in Boulder. The Boulder Amateur Radio Club sponsors "BARC Jr." for young people. Eric is vice president of that club. He also handles net control for the junior hams' net on a local 2 meter repeater. Eric successfully wrote a grant application for his school to buy ham radio equipment. The young man regularly operates bicycle mobile and has constructed an innovative J-pole antenna for his bike. He brought the antenna to the youth forum to show everyone, along with a display of photos of the BARC Jr. club members.

Mike Placco KB8LCC is a 16-year-old from Milford, Michigan. Mike was a shortwave listener first before he became a ham. He has held the position of secretary of the Milford Amateur Radio Club. Mike enjoys HF, CW, and contesting. He enjoys helping his teacher with the radio club at the local high school. I was pleased to learn that many of these young amateurs contribute to recruiting and helping programs too.

Ten-year-old Luke Ward K04IQ is from Alexandria, Virginia. The audi-

Photo A. When these three visit a hamfest, it looks more like a round-up at the OK Corral! Pictured are Cody KB5WYJ, Casey KB5UE, and dad Marty Haley AB5GU at the Dayton Youth Forum.

ence members were visibly excited when they learned that Luke has earned his Advanced license. In fact, Luke holds Novice classes for third graders. He gave a "professional" presentation with the overhead projector, showing graphs that gave statistics about children of hams becoming licensed. He helped found the Springfield Estates Elementary School Amateur Radio Club which has as one of its purposes: To provide a vehicle whereby parents, students, and teachers can share common interests and work toward common goals.

Casey Haley KB5UE and his brother Cody KB5WYJ are 8 and 10 years old respectively (see photo). Casey has a General license and Cody a Tech Plus. These two youngsters from Houston, Texas captivated the audi-

ence with their ability to communicate what they love about amateur radio. They both were introduced to the hobby by their Dad, Marty AB5GU, and Mom, Wende KB5TNU. The boys enjoy packet and CW. I've invited the Haleys to join me in June at the Texas HamCom in Arlington.

It's always a personal pleasure for me to work with youngsters from all across the country at various youth forums. This time, I was especially honored to meet and help feature such talented and eloquent young adults. I invite everyone to attend the youth forum in Texas. Come and see the best that our hobby has to offer. Come and see the future of amateur radio! By the way, Yaesu has donated a 2 meter HT to be given to a very lucky youngster at the forum. See you there!

Fixing an Argonaut 509 (Continued)

Now that I've made a complete fool of myself with the Argonaut, it's time to get down and get serious! It's also time to break out the test gear and the soldering iron, along with the manual.

Since we have verified that the Argonaut is producing 2 watts RF output, the next step is to be sure the transmitter is producing power on all bands. A quick check with the wattmeter proved all bands were producing RF. Since the problem had to be in the metering circuit, that's where I started to look.

The Metering Circuit

The metering circuit is contained on one PC board mounted to a switch shaft. You must remove the PA module to get to the SWR board. This board is not removable by unplugging it from a socket. There are many wires coming out of the board, and each is soldered in place. There is enough slack in the wires to allow the board to be moved

from its cubbyhole out into the open. To do this, remove the two nuts from the switch shaft holding the board to the switch. Be careful—they are very small and are easy to drop inside the radio.

After you have the two nuts removed, notice there are several washers and spacers on the studs. Carefully remove these and lay them aside. Now, pull the PC board back out from the shaft. After the PC board has cleared the shaft, you can pull it up slightly. If you can't move the board, don't pull it or force it to move. Doing so will break off a wire.

Since there is no indication of forward RF, then the most likely suspect would be a diode in the RF pickup sensor. In fact, the diode must be the one used to read forward power. The schematic shows this to be diode D1. It's a 1N32A type germanium diode.

Not being one to check diodes, I simply replaced it with a new diode. Don't use a 1N914 silicon diode! You'll not get the desired results if you do. You must use a *germanium* diode. If you can't find a 1N32A, then try a 1N60. Radio Shack sells a pack of 1N32A diodes for about two bucks.

After the new diode had been installed, I installed the PC board back inside the rig. You simply reverse the removal procedure. When tightening up the nuts on the switch shaft, don't get too carried away or you'll end up stripping out the threads and then you'll be in real deep dung! Finger-tighten them and then give them one full turn more.

Power up, and with the output of the rig into a dummy load, hit the tune position. Whoa! Works just like downtown! After all that messing around, to find out the problem was just a 10-cent diode takes it toll on the old self-confidence. Oh, well: One down and one (dead Argonaut) to go.

Another Argonaut Bites the Dust

This Argonaut is mine. I cooked it trying to find out what was wrong with the first one. Now, since I know the trouble was only a diode, what did I do to cook the other one? It's apparent the boards must be working correctly, but then again, look what happened the last time I assumed!

Since my Argonaut won't go into transmit, the likely spot to look for trouble would be the control board. The control board tells the other circuit board what to do and when to do it.

The control board is mounted on the top half of the Argonaut and almost directly over the meter and drive controls. It's a plug-in board with several trimmers mounted on it.

Since the control board does all the T/R switching, voltage checks on the "T" and "R" lines revealed that the "T" line was not going to +12 volts when the Argonaut was keyed. It then became a simple matter to follow the voltages as the key line was closed. After a few minutes of looking and checking, it became obvious the MPSU01 did not turn on and off as it should. Looking closer at the board and the transistor, it became quite clear why—the center lead of the transistor had broken off right at the component's base. You had to hold the board just right to see the broken lead on the transistor's body. It must have broken off while swapping control boards from one rig to the other.

Now, you can't just go down to the local Radio Shack store and get one of these critters, so a call to Ten-Tec provided me with the replacement part. In a few days they came in and within a matter of minutes the Argonaut came back to life.

Touch That Dial

If you have to order parts from Ten-Tec, always include a dial cord kit. You can always use it yourself or give it to someone else who can use one. They're not too hard to install, but it does require a complete strip-down of the Argonaut. If you have to remove the end panels you may as well replace the dial cord while you're at it.

To get more life out of the dial cord

PHASE 3D WILL BRING:

Space to virtually every ham through:

- Higher power transmitters
- Higher gain antennas
- Three axis stabilization

More bands:

- Downlinks on 10 Meters, 2 Meters; 70, 13, 5 and 3 Cm.
- Uplinks on 70, 23 and 5 Cm.

Higher Orbit:

- 48,000 km. (29,000 mile), 16 hour orbit for increased coverage and visibility for many hours each day.

PHASE 3D NEEDS YOUR HELP!

A contribution of just a few dollars from EVERY active amateur will insure that this new marvel gets into orbit.

MAKE YOUR CONTRIBUTION TODAY!

You are also invited to join AMSAT and receive the *AMSAT Journal* so that you too, can follow the progress of Phase 3D and other exciting amateur satellite activities. Dues are just \$30 annually in the U.S. and \$36 in Canada and Mexico — \$45 elsewhere.

Why buy a TNC?

PC HF FAX + PC SWL \$179.00

SPECIAL COMBINATION OFFER

For a limited time, if you order PC HF FAX \$99 (see our other ad in this issue), you can add our new and improved PC SWL 3.0 for \$80.00 instead of our regular low price of \$99.00.

PC SWL contains the hardware, software, instructions and frequency lists needed to allow you to receive a vast variety of digital broadcasts transmitted over shortwave radio. All you need is any IBM PC or compatible computer and an SSB shortwave receiver. The product consists of:

- Demodulator
- Digital Signal Processing Software
- 200 Page Tutorial Reference Manual
- World wide Utility Frequency List
- Tutorial Audio Cassette with Samples

PC SWL automatically decodes Morse code, RTTY, AMTOR, SITOR, NAVTEX and ASCII.

PC SWL lets you tune in on world press services, meteorological broadcasts, ham radio operators, coastal shore stations, aviation telex and much more digital action on the shortwave bands. Why pay for another expensive box when a simple interface and your PC can do the job?

ADVANCED FEATURES:

- Tuning Oscilloscope
- Digital Waveform Presentations
- Auto Calibration and Code Recognition
- Continuously Tunable Filter Frequencies
- Variable Shift
- Adjustable CW Filter Sensitivity
- Unattended Capture and Printing
- Integrated Text Editor
- Integrated Log and Database
- Shell to DOS applications
- Seamless Integration with PC HF Facsimile

Call or write for our complete catalog of products. Visa & MasterCard welcome.

Photo A: The Ten-Tec Argonaut 509.

when you're not using the rig, move the pointer all the way down to the low end of the dial. This removes nearly all the tension from the elastic cord, extending its life. As you move the pointer closer to the meter, you increase the pull on the elastic, thus weakening it. After awhile, when you move the pointer down to the low end of the band, the pointer will sag down into the window. At this point you'll have to restring the dial with new elastic cord.

If you made it to Dayton this year

and did not get sick from the rain and cold weather, you probably were feeling well enough to pick up a used Argonaut. If you did, and you're still hoping that someday the other guy will send you the manual, you're in luck. You can get a complete manual for just about all the Ten-Tec rigs by calling their service department. You'll get a photocopy of the manual for about \$20. Expensive, yes, but really worth the money when the Argonaut goes down.

A Sneak Preview

Dayton also provided a showcase for Ten-Tec to show off their new "Scout" transceiver. I'll have a full review in a coming "QRP" column, but here are some of the highlights of the Scout.

It's born as a monoband rig. You can change bands by swapping out a front panel plug-in module. The Scout will cover all the ham bands, including the WARC bands. Each band module costs \$25. You get the band of your choice

with the purchase of the rig. The band modules are about as long as a pack of cigarettes and about half as wide. The Scout will operate CW using the famous Ten-Tec QSK system, and of course it will cover SSB, too. Power output is 50 watts. Input power is rated at 100 watts. A QRP version of the Scout will be available down the road. The price will be about \$50 less than the QRO version. You can turn down the power of the QRO version by adjusting the ALC control. Of course, the efficiency goes in the dumper, but you'll be able to operate QRP levels with the 50 watt version if you so desire. Current at full transmit output would be close to 9 amps. This current requirement can easily be met through the lighter plug in your auto. The CPU will demand up to 1 amp sitting there. I'll have a full run-down of the current demands when I get the unit in to do the full review. A small 10 amp power supply will be available as an option for the Scout. The Scout features a very easy-to-read LED display. I don't yet know if you can turn off the display.

QRM fighting controls include the adjustable Jones filter and an RIT control. There is an optional noise blanker to combat impulse-type noise. There is a built-in keyer included, too. A nice-sized combination S-meter and RF output meter round out the features of the Scout. First impression? Looks like a winner!

SGC

PROFESSIONAL MOBILE ANTENNA HF SSB ANTENNA HIGH PERFORMANCE

For vehicles, small boats or as an emergency antenna. Supplied with stainless ratchet mount, heavy duty encapsulated stainless spring and all installation items. Including high voltage feed through insulators and wire for operation up to 10KV at 1.8 MHz.

The W9TE Crossband ATV Repeater

I've been asked many times about the pitfalls and obstacles that need to be surmounted in order to successfully build an ATV repeater. This month I'd like to offer you the story of how members of the Fort Wayne Radio Club solved both the technical and political problems involved in installing a very effective ATV repeater, as described by Jim Pliett K9OMA. The following is his account.

Finding a Site

I (K9OMA) am an active ATVer with a few years experience operating simplex. I became intrigued with the idea of building an ATV repeater in the Fort Wayne area after seeing the Indianapolis ATV repeater in operation while attending meetings of the Indiana UHF club.

One day, while driving to work, I saw an empty tower at the Indiana/Purdue campus and wondered if there was any possibility of installing our ATV antennas on it. It was located right in the middle of the Fort Wayne amateur radio community and was nearly 170 feet tall.

Now, how does one deal with the politics of a state-funded community college to obtain permission for a repeater site? Lucky for us, one of our club members worked at the college

and helped us gain a favorable position with the college board. Meanwhile, we set out writing letters to the National Weather Service and the Director of Emergency Preparedness describing how an ATV repeater could aid the community in the event of a disaster or emergency. We obtained letters of support from these organizations and presented them to the college board. After a few months of anxious waiting we not only obtained permission to use the tower but they provided us with an equipment room to boot!

We presented the idea of the ATV repeater to the members of the Fort Wayne Radio Club. We weren't sure we could sell the concept to a club that already supported two VHF repeaters and one UHF repeater, as well as sponsoring a large Field Day effort. However, since the club was recently solvent thanks to their last two successful hamfests (and probably thanks also to a few members who just wanted to end the meeting), the motion to fund the project was passed. Our first ATV repeater was getting closer to a reality!

Building the Repeater

Fortunately for us, Bruce WB8UGV had moved to the area from Dayton, Ohio. Bruce had a lot of experience with ATV repeater design since he built most of the original Dayton ATV repeater. We formed the repeater technical committee and started kicking around ideas. We have plenty of UHF voice repeaters in the area and a number of accomplished EME operators (K9KFR and AF9Y). Keeping in mind that we were the "new kids on the block" (along with Bruce's blood-curdling tales of in-band repeater problems on 440 MHz), we decided to go crossband with a 439.25 MHz input (lower vestigial sideband).

Now, did we want to go with an output on 1.2 GHz or 900 MHz? The 1.2 GHz band always seemed to be a good band, equipment was available, and the band was not threatened with extinction. However, could enough interest be generated to inspire lots of hams to go out and buy downconverters for that frequency to watch ATV? Probably not too many. A few visits to the local K-Mart and Wal-Mart stores provided us with an economical solution. The Gemini "Rabbit" wireless video system operated on the 900 MHz band and was available for under \$50 (some stores sell just the receiver for substantially less). Not only do you get a high quality downconverter, but a transmitter is included as well. With the wide availability of these inexpensive units we decided to go with a repeater output on 910.25 MHz [Ed. Note: Next month's column will describe how to install external antenna connectors on these units and tweak them up for best results.]

Photo A. The W9TE ATV repeater was on display at the Summit City hamfest just before final installation. (Photo by Jim Pliett K9OMA. The photographer can be seen on the TV monitor.)

The Antenna System

Although vertical antennas are easy to obtain or build, we opted for horizontal polarization on both bands for added isolation from all of the nearby UHF repeaters that use vertical polarization and the services in the 900 MHz band that are also vertical.

Adolph WA9WTJ was given the task of designing and building a pair of horizontal omni-directional antennas (one for each band). Adolph decided to go with an Alford slot design, which allowed the antennas to sit on top of each other. Two- and four-inch diameter thin-wall tubing was obtained from local manufacturing companies and we found some scrap aluminum stock for the support collars. The radomes were built out of drainage pipe we bought at a farm store. To maintain the necessary accuracy for the slots, we had to hire a machinist. Since we had pretty much blown the budget by now, one of our members volunteered to machine the aluminum support collars.

Repeater Assembly and Installation

All of the hardware was tested and installed in the equipment rack. After some final tweaking and two revisions of the repeater controller's software, we were finally up and running with a working repeater (at least on the testbench). See Figure 1 for a block diagram of the final configuration of the W9TE ATV re-

peater. The 5-10 watt driver amplifier was built by Bob Johnson K9KFR. Although Bob used discrete components in this design, he recommends an easier approach using a new 10 watt linear brick amplifier that is now available from Down East Microwave, Box 2310, RR1, Troy ME 04987; Tel.: (207) 948-3741 (ask for the Hitachi PF0011 module).

The 100 watt amplifier is a Varian Eimac CV2810. These amplifiers are somewhat rare, but they turn up occasionally at hamfests or in surplus stores.

Success

At last the big day arrived. The club had amassed a 500-foot roll of 7/8-inch hardline for the installation. It was amusing to watch us try to wrestle with this giant coil of coax as we unrolled it and snaked it up two floors to the tower base. School regulations required us to dig into the club treasury to pay for a bonded tower climber, however. The antenna and coax was installed without a hitch. We opted to side-mount the antenna just below the top of the tower, hoping to be a lesser lightning attractor. A few days later we carried the repeater rack up three flights of stairs, hooked up the coax and fired up the transmitter. We were rewarded with a perfect 1:1 SWR (another perfect antenna design by WA9WTJ). Bruce WB8UGV headed home and sent the first picture through

Photo B. Two Alford slot antennas (one for 439.25 and one for 910.25 MHz) are stacked on top of each other and side-mounted on the tower. Birds just love it! (Photo by Jim Pliett K9OMA).

Solid-State Surplus Amplifiers

This month I would like to cover some little gems that have recently started to appear on the surplus markets—miniature RF amplifiers. These used to fall into the general category of "UNOBTANIUM." Regular readers know that unobtainium is usually relegated to the pages of defense industry microwave journals and very tough to find in surplus. However, these miniature RF amps are suddenly beginning to show up in surplus lots more and more often.

Perhaps the most outstanding feature of these little amps is their price tag—enough to make any accountant cough. But that does not detract from their beauty because they exhibit great gain and very low noise figures. They are especially attractive if they are found in the surplus markets and have frequency ranges that cover our amateur microwave bands. One drawback to note: These amplifiers are most often hermetically sealed, making modifications virtually impossible.

I have purchased quite a few of these amplifiers so I thought I would share some of the information that I have gained from the experience. When shopping for these devices you should keep in mind the old adage: "All that glitters is not gold." Take it from me, they are not all created equal. By that I mean some make very good doorstops. If you have a blown one, you can machine the top cover off to reveal a very interesting design structure (Photo A). Many of these have intermediate stages that still function but have no output due to a fried input or output stage. Some draw no current at all. So I must advise that you make a careful evaluation of unknown amplifiers.

For many of us, these amplifiers are real strange as far as their construction goes. They are assembled by microscope, using micro positioners. Never does even a small soldering iron touch their circuits—the amps are just too small. The circuitry is usually attached by miniature gold wire and welded by

micropositioners. Take a look at Photo A. This is a picture of two amplifiers I purchased at local swap meets. For display purposes I have placed one defective amplifier, with its cover removed by a milling machine, on top of a good amplifier for comparison.

The amplifier that functions provides gain from 10.4 GHz to 18 GHz according to the manufacturer's label. But I tested it on my workbench and observed gain from 6 GHz to over 20 GHz with rolloff which was not too critical at those band edges. The remarkable thing about this amplifier is that the overall gain is 30 dB. Its maximum output power is also +30 dBm, with drive power of zero dBm. That means a standard signal generator can drive this amplifier to full output of +30 dBm or 1 watt power output. Still, this unit is so small it can fit in a flip-top cigarette box. They're quite miniature for the power and gain punch they pack. Please note that an external heat sink is required to operate these little amps.

Look at Photo A again. Upon close inspection, what appears to be large blocks centered about the direct line between the SMA coaxial connectors is actually very complex circuitry. Each small block is actually a complete push-pull transistor chip substrate circuit mounted in the space of a pencil eraser cross-section, way less than a quarter of an inch in area. A jeweler's loop or magnifying glass is needed to see this circuitry. You really have to see one in person to appreciate it. Then you can understand why they need a microscope to put these together.

The Repair Job Learning Curve

One example of a repair job that proved interesting was on the mini-amp shown in Photo A., which I opened up after it drew no DC current. Upon investigation with a magnifying loop eyepiece I found a DC input lead broken. Attempts to re-attach it with a soldering iron were met with failure. Every time I tried to solder the gold wire it melted. I tried to re-connect it to the bypass capacitor that served as the connection post for the main DC power. I used a single strand of AC zip cord to terminate on the chip capacitor. It measured only 0.15" square but was

Photo A. Two 10.6 to 18 GHz amplifiers. The unit on the top was cut open to show the assembly technique.

still very large by comparison. My attempt to re-connect the gold wire failed, and trying to solder it with a 5 watt iron (my smallest) to the top of the chip cap was futile. What finally did work (for a while) was using two common sewing needles like chopsticks. I was successful in winding the gold wire around one single strand of zip cord.

After all this experimentation, the amp that was totally dead is now drawing current but still has an output stage failure. By checking with a probe and driving the input of the amp I was able to see gain increase by moving the probe from the input stage to successive stages. Now, this is an extreme case, but consider the learning experience. It proved to be a valuable lesson of how *not* to make a silk purse out of a sow's ear. All kidding aside, it was a valuable lesson and the information gained on how it was constructed alone was worth the trouble. Systems like these and how their various components work together are often valuable tools for discovery.

Let's look at another example. This one is also a tiny amp which uses SMA connectors and fully hermetic housings. The second amplifier is also made by CIT. It has a date code of 66087. I'm not sure what it all means but it seems safe to assume the "87" refers to the year it was made. While testing this amp, I found that with -10 dBm input power driving the amp I got +27 dBm output. That's a 1/2 watt of output power. I checked out the frequency range. It was from 4 to 8

GHz—exactly as written on the label. This amp rolled off fast at its band edges.

Increasing the drive until output compression started and then just backing off a tad produced an output of 1 watt at -1 dB drive. Higher drive levels took the amplifier into compression and produced no more output. DC power requirements were +15 volts at 1.3 amps. The amplifier is linear and capable of SSB, FM or even video if you want. What you put in is what you get out. You see a true reproduction with gain, just like a linear should give you.

What does something like this cost? Well, without the quantity price breaks, similar amplifiers sell for around \$1,800. So, if you can't find one in surplus, they are available from the manufacturer. All you have to do is use some plastic credit and order one. I personally prefer to shop the surplus markets and wait for new toys to arrive. I paid \$20 for the privilege to play with this one, without guarantees.

The packaging styles that I have just described are not the only ones to watch for, but they are an indicator of what may be inside. Take Photo B, for instance. It's an amplifier from Dexcel which was made to cover 8 to 10 GHz. I had no idea what this amp would actually do, but it's still a good example of what to look for. (It cost me \$10 at a swap meet but came without a guarantee.) The first things to identify are the two SMA coaxial connectors, the single power connection, and the ground ter-

Photo B. Sample of a Dexcel 10 GHz amplifier.

Photo C. A compact CIT 4.0 to 8.0 GHz, 1 watt amplifier.

Photo D. These amplifiers were purchased at a swap meet. Sometimes you can find treasure this way, but not always.

minimal. You have to figure these SMAs are costly connectors and for a manufacturer to use them indicates they expect high performance in the microwave range because they would not waste the money on low frequency stuff. More importantly, we know this is not a filter or some other "passive device" because they provide DC power feed through capacitors, one of which is marked "+15." My rationale is: If it's not too expensive, give it a shot.

One thing to watch out for when evaluating surplus components is look-alike solid-state switching relays. They have several SMA connectors and multiple power pins. Don't confuse these with amplifiers! It's easy to make

this mistake because many are not clearly labeled. For example, a solid-state switch (SPDT) would have three SMA connectors, one or two ground posts, and two DC power pins. (One power pin is required for each direction you bias the diode switch. One is positive and the other is negative or ground. This is to allow the common continuity to the diode that is normally positively biased on with a few mA of current.) But let's get back to RF amps.

There is some risk in buying surplus, of course. You have to have faith that the seller isn't testing them all and just selling those in better need of an autopsy. In this case, with the two SMA connectors, DC power connectors, and

moderate price, I bought it. To test it I put it in my drill press bench vise, which serves as a heat sink, and applied +15 volts of power. It drew 1 amp of current. Driving with my sweep oscillator I was able to get just about 1/2 watt output with a few mW drive (+3 dBm). It was alive!

This amplifier was similar in many respects to the ones I mentioned earlier, except for size. This one was quite a bit larger, roughly 1" x 1" x 6". The point I want to make again is what to look for. The SMA connectors and power pins are the minimum requirements. Then you are on your own to evaluate what other information may or may not be marked on the prospec-

tive module you happen to be appraising.

In the case of this device, I figured out the power connector and found that when I applied DC power it drew about 1 amp. I then slowly increased the frequency on my sweep oscillator, keeping the drive level to -10 dB during initial testing. I found the output centered around the 8 to 11 GHz range. The amplifier had 22 dB gain with output power of about 1/2 watt throughout that frequency range.

Another unit that I picked up from surplus is the CIT power amp shown in Photo C. In this case, the label tells most of the story. With some units you just have to apply power and signal, but be aware that not all units will test the same. You just have to take the plunge and hope you didn't pay too much for these units. If the seller is asking for big bucks, inquire about the guarantee. If the dealer is reputable, you will be given a guarantee, or at least be allowed to test it before buying.

Testing before purchasing is a good option. It assures the purchaser that the unit operates, and also provides a good cover of protection for the seller. If a shop test is used the seller knows what is there and can prove it. With all surplus material, however, the guarantee is pretty much over at the end of the driveway. The seller is protected from someone abusing the unit or otherwise destroying it with reverse voltage in testing or some other unfore-

seen event. This seems to be a reasonable policy if the parties to this transaction are not located too far from each other.

Let's go back to the amp in Photo C. In this case the amp had all parameters posted on the unit for frequency and polarity of DC power, but gave no clue of output power or gain. On the testbench I found that with -16 dB drive (input power) I could obtain 1/2 watt at the output. By raising the drive to near 0 dBm I obtained +30 dBm or 1 watt of output power before gain compression started. That's the maximum that the amp can tolerate, as it will give no further increase in output. This amp is tiny—I placed a quarter next to it for size comparison. The unit measures 3-1/2" x 2" x 3/4".

Power dissipated is 18 watts, so an effective heat sink must be used to keep the amplifier cool. If it is not used you will destroy the unit in short order. The preferred method is mounting it on a block of aluminum with heat sink grease. Note that in Photo C there are six mounting holes for attachment to a heat sink.

Photo D shows several amplifiers I purchased at a swap meet. The long-looking devices on the bottom left and bottom right are excellent doorstops. They were high gain 5 to 8 GHz units made by Raytheon for military application, but they showed very low gain and absorbed large amounts of power from the power supply (16 watts DC). I did not follow my general rule and got

bitten on this one. I will have to have peanut butter sandwiches for a week or so to fully recover from this experience.

The other amplifiers in Photo D include a MIC amp (top left) for DC to 500 MHz, a 70 MHz IF amplifier with 32 dB gain (center top), and a homebrew 2 GHz amplifier of stripline construction. The bottom center unit is a 2.3 GHz amp, with 30 dB of gain, by Amplicia. The point in showing these is to highlight some of the various styles of amplifiers in use today. I wish you good luck locating some for yourself. Keep your eyes open at swap meets and other events. I have one friend who goes to swap meets with his wife and they snatch up everything they can find that sells for a buck or two that is small and has two SMA connectors and a power pin. True, he has an impressive collection of door stops. But so far they have only spent \$10 on junk, and about \$30 or so on real fine units.

Of course, the market is not limited to just amplifiers like these—they may be the exception. Other types are available; you just have to keep your eyes open. I have been able to pick up amps that work in the range of 30 MHz to several GHz. They are all usable—I use the low frequency amps for IF work and the higher frequency amps for RF work. If you are as lucky as I have been you will soon have more amplifiers than you can use. Your worst problem will be trying to store all

this stuff. That's why I stress *small* on my list of requirements.

I violated this rule at the last swap meet when I found a unit that weighed over six pounds, heat sink included. It had a BNC and an N connector with power pins. The price was right, so I picked it up. It was covered with grimy dirt from the blower attached and lots of use. The label on top of the unit was obliterated and defied identification. The object on the heat sink was only 6" square and 1-1/2" high—very small for the heat sink it was attached to. I removed the basic unit from the heat sink and removed the 35 4/40 screws holding the top cover down. What I saw upon lifting the cover defied reason: It was a very complex microwave transmitter complete with oscillator.

After intense investigation I determined that this unit was a video transmitter converting video to RF directly. Internally it had two duplexers for two channels of audio to ride along with the video. Since it was about eight years old it used transistor frequency multiplication to about 1.7 GHz, where it fed a dual-channel, high-power varactor multiplier. The interesting part of this story is that when I applied 24 volts DC power, it drew 4 amps and put out +43 dBm at 4.9 GHz into a dummy load. Power of +43 dBm is 20 watts of power! Looks like the unit is good from 4 to 5 GHz so plans are in the making to see if it can be adjusted to the 5760 ham band as a video transmitter. What else can you say but, "WHAT A GOLD

MINE!" It doesn't happen all the time, but sometimes it does happen. Now if I can only figure out the lottery numbers . . . just dreaming.

Mailbox

Jack N700, of Serria Vista, Arizona, wants to use 10 GHz full-duplex on a data link for experimentation. He has several intruder units manufactured by Raycom to test. His transmit units run on 78 volts DC. Can these units be modified? Well, Jack, it sounds like you have an Impatt diode oscillator, indicated by the 78 volts. That's what these diodes take for operation, 75 to 100 volts DC. Each diode has a specific critical voltage to set oscillation current—limited to a particular mA value for that diode.

Some units have to be adjusted lower in frequency by metallic screws penetrating further into the cavity. I have seen some Impatt sources that require dielectric tuning screws which have to be inserted into the cavity to do the same thing. In that case we used a Nylon 10/32 screw to do the required tuning. A little experimentation is needed to solve your particular unit's frequency adjustment. I just have not seen these Raycom units.

Well, that's it for this month. Next month I plan to get into another type of amplifier, the Log Amp. As always I will be glad to answer any questions relating to this or other aspects of VHF-to-microwave operation. Please send an SASE for a prompt response. **73**

PCB / Schematic CAD - from \$195

EASY-PC - For single sided and multilayer boards to 17"x17". Phenomenally fast and easy to use. Over 14,000 copies sold.
EASY-PC Professional for boards up to 32" x 32" at .001" resolution, 16 layers. Schematic capture and netlist extraction - integrates seamlessly with PULSAR and ANALYSER III. Demo disc available.

Logic Simulation - from \$195

PULSAR and PULSAR Professional - Full featured digital logic simulators. Allow you to test your designs quickly and inexpensively without the need for sophisticated test equipment. **PULSAR** can detect the equivalent of a picosecond glitch occurring once a week! Demo disc available.

Analogue Simulation - from \$195

ANALYSER III and ANALYSER III Pro. Powerful linear circuit simulators have full graphical output, handle R's, L's, C's, Bipolar Transistors, FET's, Op-Amp's, Tapped Transformers and Transmission Lines etc. Plots Input and Output Impedances, Gain, Phase and Group Delay. Covers 0.001 Hz to >10GHz. Demo disc available.

The End of Oscilloscopes

For the past couple of months, we've been examining the nitty-gritty of using that wondrous window into the wacky world of electrons, the oscilloscope. Let's finish it up.

Just a Short Delay

OK, you've got your waveform frozen on the screen. Great! You're all ready to go. Hmmm, the part you want to see is awfully small and squashed. Wouldn't it be nice if you could stretch it all out? Well, sure, you can speed up the sweep, but it's kind of annoying to have to switch it back to where you were after you're done. For quick time base increases, most scopes have a "time base magnification" button. This multiplies the speed of the time base by 10 (or sometimes by 5, depending on the scope) and lets you return to your original setting just by pressing the button again.

Uh oh, wait a minute, now the part you want to see is off the right side of the screen, lost in space somewhere. How do you get it back? Slow the sweep back down. But now everything's so crunched together that all the detail is lost again; it's just a tiny blur and you're right back where you started. It would seem like there's no way out of this dilemma, but there is. It's called *delayed sweep*.

What you really need here is to trigger on your selected trigger point but not start sweeping until later on in the waveform, right? Delayed sweep lets you do that. First, you set up your waveform so that what you want to see is on the screen, but too small. That way, you know you have a stable trigger point. Then, you use the delayed sweep controls, which are just like the main time base controls, to start the sweep later in the signal. The effect is like looking through a magnifying glass. As you turn the sweep delay control, the signal zooms past as if you had a really long screen. Any time you work on a signal whose period of repetition is very long compared to the high frequency components (again, a TV signal is a great example), delayed sweep is an absolute necessity. There are lots of low-cost scopes that don't include this handy feature, but I strongly recommend you get a scope that has it, even if you don't see a need

for it now. You will, I promise.

Cursors

Some newer scopes provide on-screen cursors which let you select various points in your waveform for measurement. You can, for instance, easily measure the time between any two points or select a point and read its voltage. Usually, the result is drawn numerically right on the screen. Although these cursors don't give you anything you can't get yourself with a little more work in interpreting the screen, they speed things up and take some of the burden off of you. They're nice but unessential. And they usually add a few hundred dollars to the price of a new scope.

Memories . . .

Light the corners of my workbench. Well, not my workbench, but some people's, especially if they have a fair amount of money. I'm referring to digital storage, which, for some applications, provides the ultimate in oscilloscope utility.

Digital storage scopes have been around for many years, but they still are too expensive for most of us. I've never seen one at a hamfest, either. (But I keep looking!) Digital scopes work in the same way as any other digital recording devices. They use an analog-to-digital (A/D) converter to digitize the incoming signal. Then they store the bits in memory. After that, the information is read out and displayed as a trace on the screen. Why bother? The beauty of the system is that you can do things to those bits while they are in memory. You can measure the values they represent, perform mathematical operations on them to remove noise, or do just about anything you can imagine. Also, you can keep those bits as long as you like and even store them on a disk without any signal degradation. And, your input signal can be a one-shot event and you can still see it long after it's gone! Sounds like electron utopia, huh? Well, not quite . . .

A Mess By Any Other Name

In order to accurately represent a signal in digital form, you have to sample it at a rate that is at least twice as fast as the fastest component of the signal itself. This basic tenet of sampling theory, called the Nyquist Rule, is the reason why compact discs sample at 44.1 kHz (because the highest audio frequency of interest is 20 kHz). It is also the reason why digital sampling devices

always have low-pass filters at their inputs to reject any incoming signal components which are faster than half the speed of their A/D converters. It's absolutely necessary to do that because, if any of the unwanted signal frequencies get through, they will cause incorrect A/D conversion and result in an odd form of signal distortion known as "aliasing." Aliasing is the electronic equivalent of the strobe effect. You've seen that any time you've watched TV or a movie and seen car or wagon wheels appear to go backwards. The wheels were going much faster than the frame rate of the sampling device (TV or movie camera), so portions of their rotations were missed between frames. The result is that the wheels' positions were depicted at various points along their paths, implying a speed or direction of rotation which never really occurred. That's aliasing, and it can make an electronic signal appear totally different than it really was.

Equivalent Is Not Equal

On a digital scope, the limiting factor in the instrument's ability to "grab" fast signals is the speed of its A/D converter. Just a few years ago, an A/D converter which could digitize megahertz-rate signals was prohibitively expensive. We're talking hundreds of dollars here, just for the converter. So, in order to make commercially viable digital scopes, designers turned to a compromise method called "equivalent-time sampling." In this technique, the converter is made to sample a small piece of the signal which has been frozen in a preceding circuit called a "sample and hold." Each time the signal repeats, the converter samples the next small chunk, building up a digital representation of the total signal over many periods. This method of using a sluggish converter to digitize a fast signal does work, but it has a big disadvantage: The signal must repeat, and be exactly the same, over a fairly long period of time or the resulting digital representation will be wrong. So, equivalent-time sampling works fine for simple things like sine waves, but it is useless for complex waveforms which change a lot, like TV signals or digital pulse trains. Still, it is handy.

These days, 20 MHz converters are fairly cheap, and even faster ones are coming down in price all the time. So, a true-sampled 10 MHz scope is not prohibitive, and that same scope can offer equivalent-time sampling to perhaps 50 MHz or more.

Because of the aliasing issue, digital scopes take more understanding to use than do analog units. The only way to be sure you're really seeing the truth is to have

some idea of what *should* be there in the first place!

Some scopes offer both digital and analog modes in the same box. They ain't cheap, but they offer the best of both worlds. Ah, if I only could afford one . . .

The Future

Considering the proliferation of pocket LCD TV sets, you might wonder why you can't buy a pocket LCD oscilloscope. Well, you can! That is, if you have some serious bucks. I've seen ads from two companies making them. One sells for about \$1,100, and the other, with more speed and features, goes for about \$2,000. As E.T. said, "Ouch." I strongly suspect that, if more people knew how to use scopes, the market would drive the price down and we'd see \$100 basic LCD scopes at Radio Shack, just as once-exotic digital multimeters can now be had for as little as \$25. I know I'd be first in line to get one.

Also, there have been several "computer scope" products which allow you to use your personal computer as a scope. These boxes contain the A/D and other required hardware and present digitized information to your computer, where application software lets you manipulate and display it. It's a great idea. About six years ago I had a computer scope made by Heath. It worked great but I strongly disliked using it, primarily because it used a serial interface at 9600 baud, resulting in slow, snapshot-like traces on the screen. Also, it had a slow A/D and relied heavily on equivalent-time sampling. A good, fast, converter and a parallel or SCSI interface would have made all the difference. Still, it was a useful, if frustrating, box.

Well, I think we've covered just about every knob and button on an oscilloscope. I hope I've enticed you to think about getting a scope, or to pull that dusty one out of the closet and fire it up. Now, let's look at a few letters:

Dear Kaboom,

My KDK FM-2033 transmits but does not receive. After awhile it comes back to life and works fine. I checked for bad solder joints, but no luck. I don't have the manual, and KDK is no longer in the US. How can I fix this thing?

Signed,
At A Loss

Dear At,

I'll bet if you measured the frequency of the rig's transmissions when it is not working, you'd find they were nowhere near where they should be! My bet is that your PLL is way out of lock and, for some rea-

son, the rig's out-of-lock detector is not catching it. It could be as simple as an adjustment, but I can't suggest anything because I, too, have no access to a manual for that rig. I strongly recommend that you put a notice out on packet and try to get a manual. Good luck—I hope you find one.

Dear Kaboom,

About five years ago I bought a Mollicell rechargeable-lithium battery pack for my ICOM handheld. I still have it and it still works great! I once left it for six months and it retained about 85 percent of its charge. It seems to have no memory problem and is trouble-free; it's much better than NiCds. I'd like to buy another one but the supplier seems to have disappeared. What happened to this excellent product?

Signed,
Unrequited Love

Dear Unrequited,

I remember the Mollicell. In fact, somewhere I still have a key chain the company gave me at a product demonstration. Yes, they were great batteries. Unfortunately, they were quite a bit more expensive than NiCds. I don't know if that's the reason they didn't catch on, and I don't know if Mollicell is still in business or not. I do know that Sony has a rechargeable-lithium battery on its latest high-end mini camcorder, so the technology is not dead. If any of you out there know the status of Mollicell or their wonderful batteries, please let me know and I'll pass it along here in the column. Until next time, 73 de KB1UM.

Notes from FN42

Hey, guess what! Someone has been reading my column and told me the other day that he was taking my advice to get involved with helping others in ham radio. But, this guy has been very actively involved already. Gary KD1JR got involved from the very beginning of his amateur career, which hasn't been very long. He progressed through to Extra within a year and has been going hard ever since. And, not too long ago, he decided to get involved in the MARS program to be able to provide phone-patch service to many of our service people. Thanks, Gary, and keep up the good work! There's lots more news this month, so let's get to it! 73—Amie, N1BAC.

Roundup

Brazil This is a little bit late, but The Antenna-Electronics Popular magazine sponsored the World Wide South America CW Contest—WWSA/1993 June 12-13, 1993. Send your logs (with SAE/IRC for results) by July 31 to WWSA Contest Committee, PO Box 282, 20001-970 Rio de

Janeiro, RJ, Brazil. The WWSA CW Contest was created in 1982 and takes place every year on the second complete weekend of June. The WWSA is supervised by the well-known CW Groups Pica-Pau Carioca (PPC) and Morse Clube Gaúcho (MCG).

Republic of Korea Letter from Charlie R. Hopkins HL9FY: Hello to all! I am stationed at Osan Air Base with the United States Air Force. We have a very active amateur radio club, the American Amateur Radio Club of Korea. We have members who attend our meetings from all over the Korean peninsula. I am the treasurer of this organization and the volunteer examiner coordinator liaison for the ARRL testing group. I have been in Korea this time since December 1987 and am currently serving on my seventh tour. I got my original amateur radio license in May 1983 and came to Korea in August 1983. Shortly after my arrival, I requested a HL9 callsign. Prior to my departure from the U.S.A. in 1987, I wrote to the office responsible for issuing licenses to U.S.A. personnel in Korea and was fortunate enough to get my old callsign back, HL9FY. I wish to inform you that some people coming to Korea can get an amateur radio license. There are

Photo A. The Young Operators' International Club's logo.

some requirements to be met. Before a person is eligible to get a HL9 callsign, they must be covered under the Status of Forces Agreement (SOFA) between the governments of the United States and the Republic of Korea. If they meet this criteria and have a valid U.S. callsign, they can apply for an operator's permit and get a station authorization.

Operating in Korea is a little different from operating in the U.S. There are no portable or mobile operations permitted for HL9 licensees. There are no (repeat, no) CB operations allowed

in Korea for foreigners. Furthermore, the installation of radio equipment (amateur or CB) in a privately-owned or government vehicle is prohibited.

The frequency allocations are different on some bands. Power is limited to 500 watts for the Extra, Advanced, and General Classes; 100 watts for the Technician Class; and 50 watts for the Novice Class. Just about all modes of operation are permitted: SSB, CW, RTTY, packet, SSTV, FM, and beacons, just to name a few. You must also maintain a log of contacts. A license, once issued, is valid until the

person's DEROS (date of estimated return from overseas) is reached, the individual's stateside license expires, or the person leaves the country on a permanent change of station (PCS). If a person reaches his DEROS date but is extended, he or she must renew the license before the expiration date. The license date is not automatically extended with the service commitment extension. Any person coming to Korea who is covered by the SOFA agreement and would like more information on amateur radio operation may contact either myself or Mr. Andrew Lamb at the following addresses and phone numbers: SMSgt Charlie R. Hopkins, PSC #3, Box 5314, APO AP 96266-5314, 011-82-333-661-4750 (2300Z-0700Z), 315-784-4750 (DSN), 011-82-333-661-4620 (24 hour FAX), 315-784-4620 (DSN FAX) or Mr. Andrew F. Lamb, ACoS J6, ATTN: EAIM-O-OMT, APO AP 96205-0010, 011-82-2-7915-4160 (2300Z-0700Z), 315-725-4160 (DSN), 011-82-2-7913-3052 (24 hour FAX), 315-725-3052 (DSN FAX). Mr. Lamb or I can answer anyone's question(s) concerning getting a license in Korea. Please feel free to call or write if you need information. The phone numbers are listed as they would be dialed from a commercial phone, unless indicated as DSN. If you write, please note that an APO address is just like a stateside address and does not require international postage. Usually a three-to-four-page letter will only require one 29-

cent postage stamp.

On a final note, a person may not apply for a HL9 callsign until they are physically in the country. So, if you are coming to Korea, pack up your rig and plan on getting on the air when you get here. A license can be processed in as little as 15-20 minutes. *[Wouldn't that be nice here in the U.S., rather than 6-8 weeks or more?—Arnie]* Andy and I are looking forward to hearing from the future HL9s and welcome you to "Korea: Land of the Morning Calm." 73 from Charlie HL9FY, AARCK Treasurer, AARCK ARRL VE Liaison.

Russia Letter from Andrei Trubachov UA3PIP, organizer of YOP: The Young Operators International Radio Club (YOP). The YOP is an international organization of young people, intended to promote friendship and a better understanding of one another by sharing ideas about radio and other hobbies through radio communication and a newsletter.

The idea of organizing the club came to me after about five years of activity on the ham bands. While trying to improve my English by talking with other operators, I found that about 95% of them were over 40 years old, particularly on CW, where after a number of contacts I began wondering if radio was just a place for retired people! This age difference is probably one of the reasons why the young guys I met became such good friends. So, why not try to bring young

hams and SWLs together through an international radio club? This would be a good opportunity for them to communicate, since many have VHF-UHF licenses or only receivers. Also, the boys and girls who are not yet licensed and are trying to get into amateur radio would be welcome to the club. A newsletter or small magazine will be published so that members may share their ideas about radio, as well as other interests, including computers, travel, music, etc.

So, if you are under age 30 and enjoy ham radio, join us and let's have fun together! Send your photograph and a brief description of yourself to: Mike Page! WB9QFW, University of Wisconsin, Stevens Point, WI 54481 U.S.A. [Andrei "Andy" Trubachov UA3PIP, 301264 Russia, Tulsakaya Obl. Lipki, UL Gagarina 10, K. 14]

1 Kings Road
Hong Kong
Eric Lee VS6EL, a keen and enthusiastic amateur since 1977, is up and leaving for Australia. By the time you read this he will have set up home in Sydney. We are sorry to see you leave us, Eric, but wish you well in your new home and hope that we shall be hearing from you when you get on the air soon.
Christmas is behind us and both clubs had excellent Annual Dinners. As

a result, talk is already in progress about next year's dinner. It was noted that perhaps we might have a joint Annual Dinner, but at a recent meeting of ELARCS it was felt that, as this is the only major social event of the year, and because we did not wish to lose our identity, the vote was all in favor of retaining our existing arrangement. We have already made a booking for the first weekend in December at the Royal Hong Kong Yacht Club again. This does not mean to say we would not wish to have a joint annual event. It was suggested for further discussion between HARTS, JAROC.NH, and ELARCS that perhaps a Spring Chinese Dinner might be the way to go in 1994, without chasing door prizes but just to have a pleasant social gathering of all the various elements of amateur radio under one roof. If you, our readers, have any ideas or proposals in this matter, please approach your club committee members with your ideas.

developed in my country in so many different areas. I don't know for sure, but I would hazard a guess that I'm your most veteran Hambassador still appearing regularly in the column without a break.

For the record, I am 43 years old, married with one child, an electrician by trade, have been a farmer, and still participate from time to time in the agricultural ventures of my kibbutz. I've held a ham license since 1965, RF being a long-term addiction that I have not succeeded in shaking. I've dabbled in many facets of the hobby over the years, including 160 meters DXing and general HF Dxing and rag-chewing, and built all my own antennas. My latest interests in the hobby are satellites (mainly OSCAR 13) and VHF packet. I am also an artist, with paintings mainly, but not exclusively, celebrating the plains of the western Negev region of Israel. Some of these paintings may be found in private collections in Israel, Holland, the U.S., and Canada.

From time to time a reader will write me with a specific request for information or with a desire to set up a sked. The demands of a busy, working life do not allow me to accede to all these requests as time is a very scarce commodity. However, over the past 10 years I believe that I have covered almost every facet of Israeli amateur radio, and looking up the back issues of 73 will provide most of the answers.

OKINAWA, JAPAN

FPO AP 96372-0840

The China Radio Sports Association strongly encourages home-brewing by Chinese hams. One enterprising Chinese ham in Shandong Province found a pre-1949 ham radio book and built a working, but unfortunately chirpy, two-tube transmitter with which he worked Chinese and foreign stations. Unfortunately, the parts, the test equipment and the level of these beginning Chinese home-brewers are not good enough to build home-brew equipment which meets the strict Chinese signal stability and bandwidth requirements. A *CQ Taiwan* ham magazine article concludes that once Chinese hams are able to buy fairly simple transceivers, their persistent efforts to learn foreign languages and CW will put them in touch with hams worldwide. The author predicts that Chinese ham radio will one day be as flourishing as Japanese ham radio.

Sending Chinese hams copies of some of the best home-brew construction articles which have appeared in US, Japanese, and other ham magazines is one way foreign hams can help. The language barrier and the difficulty of adapting a design to locally available parts are obstacles to the Chinese home-brewer, however. Perhaps Chinese magazines could reprint

some of the best articles from foreign ham magazines if reprint permission could be arranged.

There is now no national ham magazine in the PRC. One very popular radio and electronics magazine, *Wuxiandian [Radio]*, published by the China Electronics Association and the Renmin Youdian Chubanshe, does devote a few pages to ham radio each month. The address is *Wuxiandian*, Dong Changan Jie 27, Beijing, China. Perhaps ham magazines outside China could arrange with *Wuxiandian*, and whatever other Chinese radio, electronics or ham magazines that will soon appear, to exchange permissions for non-exclusive translation and reprinting of articles without prior notification, just as 73 and the CO Publishing Co. of Japan have done for several years. In this way, the Chinese magazine can make whatever parts substitutions and design changes are needed so that Chinese readers too can find the needed parts more easily and cheaply in their own area. A subscription to this Chinese language electronics repair technician oriented magazine can be obtained through the Joint Publishing Co., 9 Queen Victoria St., Hong Kong.

The China Radio Sports Association (CRSA) wrote the "Provisional Rules for Regulating Individual Amateur Radio Stations" at the request of the Chinese government to provide a framework which permitted the start of individual amateur radio station opera-

tion using the BA, BD, and BG prefixes on December 22, 1992. These rules provide that all hams shall be a citizen of the PRC of at least 18 years of age, that radio equipment meet national radio emission standards, that the equipment and station be inspected by the provincial or special municipality CRSA, and have proper documents from the CRSA when buying equipment, home-brewing or modifying equipment. The rules require on-air politeness, exchange of QSLs for international contacts, and forbid the use of amateur radio to promote business, political or religious activities. Amateur prefixes indicate license class: BA is for a First Class licensee; BD belongs to a Second Class licensee; and BG is for a Third or Fourth Class licensee. These new home ham stations are often home-brew and run low power. Listen for them!

der to avoid getting you confused. I am Chinese.

TUARC SPECIAL EVENT '93 . . . Having received the formal approval from the State Sports Commission of China, TUARC is going to establish a special event station—BT2000BJ—May 23 through 31 and July 1 through 31. This somewhat different callsign is exclusively dedicated to showing our wholehearted support to Beijing's bid for the 2000 Olympic Games. We will mainly operate on the SSB phone mode (and also CW and RTTY) on practically all HF bands, including 12, 17, and 30 meters, especially 10 MHz CW. This might be the very first time "BT" is on the WARC bands. TWINS . . . Failure and Success are twins—this is exactly what we have learned from the recent antenna construction. With an outstanding book on hand and with Dieter/DJ7BU's professional instruction, we got a Zepp antenna built and working on March 20, but later the haphazard weather during this time of year caused some more trouble and crushed our well-designed, good-looking cubical quad on April 18. Thanks to Dieter's confidence and our perseverance, we quickly recovered and bettered the two old beams on April 25. Another dipole was getting the attention of passers-by on May 1, a real "Labor Day." The original ground plane will remain and we may put up an inverted V before the BT2000BJ Special Event.

CLASSROOM . . . The antenna is

"everything" for working DX, but not everything for getting skilled ops to work DX. In order to get fully prepared for the high likelihood of pile-ups during the BT operation, Rick has started a 2nd session of the TUARC Amateur Radio Class and has gotten 15 more students involved. All of this group of boys and girls have a good command of English and a cooperative and progressive nature.

BT5HPW . . . Assisted by the Xinhua News Agency in Hong Kong, the Young Pioneers of China and the Hong Kong Girl Guides jointly started their North-American-Indian-type camp life in Hangzhou on April 5. A TS-50S and an AT-50 automatic antenna tuner were carried to the camping site, and the Special Event callsign BT5HPW remained busy on the air until the 19th of April.

LARRY AND JIMMY . . . Rick had a lovely chat April 30 with Jimmy BV4AS/7 and Larry BV7/N4VA, who were on their way to Penghu Island near Taiwan. Larry, as an American volunteer and the ITU Region 3 Coordinator, had just come back from his CW teaching in Bangladesh (S21). We wish Larry the best of good luck in whatever he'd like to undertake in the future and will look forward to learning Morse code from him sometime soon.

SUNSHINE COAST . . . TUARC is very grateful that the Sunshine Coast Amateur Radio Club (SCARC) in Australia sent out a quick response to our ham-related magazine request. Rick

Photo B. Ron Gang 4X1MK, who has been 73's Ambassador to Israel for 10 years.

was happy to be informed by Ron VK4DRC and Joe VK4GEL that a package has been sent via surface mail. "ALMOST" HAM VISIT . . . While busy working a European pile-up on April 3, Rick heard, "Hi Rick. This is Ken G3OCA, and I'm flying to Beijing May 5." Ken did make the trip but, because of a temporary change of his tour schedule, we were unable to have

an eyeball QSO. TUARC would like to thank Ken for the nice info and we'll see you next time.

Thank you for reading China Ham News. Any of your comments and/or suggestions are appreciated. If at any time TUARC can be of help to you, don't hesitate to ask. Remember that you have quite a few friends in Beijing.

HAM HELP

Number 25 on your Feedback card

We are happy to provide Ham Help listings free on a space available basis. To make our job easier and to ensure that your listing is correct, please type or print your request clearly, double spaced, on a full 8 1/2" x 11" sheet of paper. You may also upload a listing as E-mail to sysop, to the 73 BBS/Special Events Message Area #11. (2400 baud, 8 data bits, no parity, 1 stop bit, (603) 924-9343). Use upper- and lower-case letters where appropriate. Also, print numbers carefully—a 1, for example, can be misread as the letters l or I, or even the number 7. Specifically mention that your message is for the Ham Help Column. Please remember to acknowledge responses to your requests. Thank you for your cooperation.

Manual/Schematic? B&K 445, EICO 379, EICO 330, SEMCOR RC115, TS-888. Marvin Moss W4UXJ, Box 28601, Atlanta GA 30358.

I am a Grade 7 teacher and for the past three years have been teaching Ham Radio as an extra-curricular class for Grades 6 to 9. On May 2, 1993, our supply room was broken into and the majority of our radio equipment, which consists of VHF and UHF gear, was stolen. Because of our limited budget, this equipment cannot be replaced, and therefore, we are seeking donations of any type. Your help will be

greatly appreciated. I will reimburse shipping and any other costs incurred. Please forward to Jay Goldring, 327 Seneca Ave., Burlington Ontario, Canada L7R-2Z8.

Wanted: Simple, inexpensive receivers or transceivers for 5.735 MHz USB, for 12 volts DC or less. Could be in kit form. Needed for use in Zaire, Africa for communication between churches. What are the possibilities? Keith Gustafson KB0DRU, BP 1377, Bangui, Central African Republic, Africa.

Can anyone provide me with schematics or manuals for the Gonset G-66B mobile receivers? I will gladly pay reasonable fees. Al Cikas KA9GDL, 412 Radford Dr., Sherman IL 62684.

Needed: Manual and schematic for a Tempo One SSB Xceiver. This is the Yaesu "white face" unit with transistorized VFO. I will gladly pay reasonable copy and shipping charges. Thanks and 73's. *Pretty Ogletree NONMC*, 3609 Bray Ave., Columbia MO 65203-0877. Tel. (314) 445-2662.

I am looking for info, manual and schematics, for a D&A Maverick HF amplifier. I have been unable to contact the company. If you can help, please call *Jim Hassen KB3ANX*, (301) 422-1209.

Dealers: Your company name and message can contain up to 50 words for as little as \$420 yearly (prepaid), or \$210 for six months (prepaid). No mention of mail-order business please. Directory text and payment must reach us 60 days in advance of publication. For example, advertising for the April '92 issue must be in our hands by February 1st. Mail to 73 Amateur Radio Today, 70 Rte. 202 N, Peterborough, NH 03458

Blanchette Park, 6:30 AM-2:30 PM. Vendor area open 9 AM. Talk-in on 146.071.67. Contact *Scott Schultz N0UVM*, 241 Burning Leaf Dr., St. Peters MO 63376. Tel. (314) 928-7267. VE Exam pre-registration: (314) 524-3254.

NEVER SAY DIE

Continued from page 4

mainly made equipment for the military.

I'd just started 73, so this bomb almost put my fledgling magazine out of business. Worse, the ARRL proposed rule change also discouraged school radio clubs and almost 100% of them folded up.

That's when we lost our infrastructure... our main source of new hams. Up until that time 80% of our new hams had been teenagers, according to an ARRL study. Fifty percent of the newcomers were either 14 or 15 years old. Further, the study also showed that 80% of these newcomers went on to high-tech careers as a result of their interest in amateur radio. Thus, once we lost our source of new hams, our communications and electronics industries lost their major source of recruits. I don't know how much this contributed to our loss of consumer electronics industries to Japan, but there's no way this could have made things better for us.

So here we are in 1993. I'm not really sure what good reason there is for our hobby in today's world and as we are running it. We have little need for the Morse code any longer. We have little need for much in the way of electronics education since we are building little and repairing not. Thus, if our exams are going to be relevant to what we're actually doing, what kind of questions should be asked?

We do want ops to know the rules, even if many ignore or flaunt them. And we'd like them to know how to be good operators, even if their personal crazy-

ness keeps them from doing this. It would be nice if they had a concept of how our bands are laid out and how each one works. Perhaps we should ask that they have an understanding of how the various modes work... what FM and AM mean. How SSB works. How RTTY and SSTV work. How packet works. How to make satellite contacts. How repeaters work. Things like that. It could be helpful if they had an understanding of antennas and how to tune them. They might burn out fewer finals. And how about knowing how to tune receivers? And how to keep from turning up their compression control and messing up the band?

I wonder if we might be able to include at least a basic course on how to talk, something that has been sadly needed for years? We've got rag-chewers who've been saying the same stupid things for years, without one ounce of brains showing through. Their rag is so thoroughly chewed it's about dissolved.

The code. Yes, I know we need some sort of filter to keep the good guys out and let in as many crazies as we can. The code has served this purpose admirably for decades. I see where an Extra Class licensee just had his ticket pulled for transmitting false distress signals. Two other Extra Classers were put in prison for bad language on CB. Another took a gun and shot his co-workers. Great filter we've been using. The only fairly sane Extra Class licensees I know cheated to get their tickets using the Bash system.

Yes, I know all about the ITU requiring a knowledge of the code for operation under 30 MHz. I also know that the ITU

does not specify any speed, so we could just as easily let 5 wpm be the only code speed we check for all classes of license. The nice thing about 5 wpm is that you don't even have to be able to copy the code to pass a test at that speed. You can just write down the dots and dashes and then decipher them at your leisure. It doesn't take much effort to at least learn the code characters. I did it one night when I was 12 and was getting dressed to go to a Boy Scout meeting. Took maybe a half hour, tops, and I've known 'em ever since.

It doesn't take long to memorize stuff like that. I had to memorize the Greek alphabet during a fraternity initiation. That took maybe 10 minutes and I've known it ever since. Now and then it comes in handy. Handier than the code ever has.

The Up and Down Sides

What would be the benefit of going to one class of license? Well, it would save a lot of money and a lot of aggravation. It would also result in our having a lot more hams. And that, in turn, would result in our having more political clout.

Oh, my God, think how crowded the bands would get! Maybe. On the other hand, we need some pressure to get us to use the 99.9% of our allocated bands which we are flat out not using yet. We also need some kind of pressure to get us to invent and pioneer some more spectrum-efficient modes of communication.

Oh, we moan and groan about 450 MHz being packed solid. Baloney. It's packed solid with little-used repeater links which could just as easily be moved to 10.5 GHz, where hundreds of them

could all share one single frequency, using directional antennas to prevent interference.

We're busy fighting each other for DX, creating pile-ups and worldwide bad feelings. Some fairly simple digital techniques could resolve this mess in a hurry. For that matter, once we go digital, we'll be able to have our stations make DX contacts for us automatically in about a second and we'd be able to work all 400 countries in one day. This might even make it so those of us who have learned to talk might be able to enjoy actually talking with chaps in rare spots around the world.

I can hear the croaking chorus of old-timers now. If we open the gates our ham bands will be as bad as the Citizen's Band. Only hams who have (a) not listened to our bands in several years and (b) not listened to CB in years could say such a dumb thing.

Of course I don't think I've proposed making the ham ticket as easy to get as buying a CB rig, so I doubt we're going to be attracting very many Southern truck drivers. But then here you are arguing with me about how bad this would be and you haven't asked me what I'm proposing in the way of a license test barrier.

I know it's unpolitic to even suggest that there are classes of people in America. Well, Vance Packard many years ago described different classes and did a good job of it. We do have different classes and they stay fairly separate. In fact, they are less flexible these days than they used to be a generation or two ago. It used to be much easier to move up in class.

18th Annual Va. Beach HamFest / Computer Fair™ & PopCom SWL Convention ARRL Virginia State Convention

Oct. 2 & 3, 1993
Va. Beach, VA

- ✓ Major Commercial Exhibitors & Dealers
- ✓ Amateur Exams & Upgrades
- ✓ Special Guests - Gordon West, WB6NOA & Roy Neal, K6DUE
- ✓ DX Forums - Technical Forums
- ✓ Major Computer Dealers
- ✓ Excellent Food Service
- ✓ Held at the Va. Beach Pavilion
- ✓ Plenty of FREE Parking
- ✓ It's still Vacation Time at the Beach!
- ✓ Lots of Nearby restaurants, museums, historic sites - Williamsburg, Busch Gardens, Norfolk Naval Base & more!

General Admission - \$5 Advance - \$6 At The Door
Tickets Good for Both Days!

CIRCLE 278 ON READER SERVICE CARD

INTRODUCING THE UNIVERSAL M-400 A totally new concept in code / tone readers!

- A RTTY-reader and tone-decoder in one!
- Easy to read two-line 40 character LCD.
- No computer or monitor required.

- Baudot
- Sitor A/B
- ASCII
- Swed-ARQ
- FEC-A
- FAX
- POCSAG
- GOLAY
- ACARS
- DTMF
- CTCSS (PL)
- DCS (DPL)

Forget the limitations you have come to expect from most "readers". The self-contained Universal M-400 is a sophisticated decoder and tone reader offering an exceptional range of capabilities. The SWL will be able to decode Baudot, SITOR A & B, FEC-A, ASCII and SWED-ARQ. Weather FAX can also be decoded to the printer port. The VHF-UHF listener will be able to copy the ACARS VHF aviation teletype mode plus GOLAY and POCSAG digital pager modes. Off-the-air decoding of DTMF, CTCSS (PL) and DCS is also supported. The M-400 can even be programmed to pass only the audio you want to hear based on CTCSS, DCS or DTMF codes of your choosing. The M-400 can run from 12 VDC or with the supplied wall adapter. The American-made Universal M-400 is the affordable accessory for every short-wave or scanner enthusiast.

Only \$399.95 (+\$6 UPS).

The classes are divided by language, kinds of homes, the clothes they wear, the clubs they belong to, the kinds of cars they drive, their furniture, the foods they eat, and so on. Hams, as I mentioned, tend to center on lower middle class, with almost no lower class people attracted to the hobby, and only a few of the upper middle class. We have a few doctors, lawyers, and business executives, but very few of these are particularly high-earners. Hams tend to center in the \$35,000 to \$65,000 family income range.

The positive side of this sociological excursion is that, being of a similar class, hams tend to be able to get along with each other easily. It results in our ability to talk about things of common interest during our contacts. We tend to have common backgrounds. If you've ever attended a major hamfest or convention you can see this... particularly when you compare the mix of people with a CB convention. Different group of people entirely. So it's no wonder hams tend to look down on CBers. We haven't completely eradicated class consciousness in America yet.

Taking all that into consideration we have a little problem for you to talk about and come up with some ideas. If we're going to continue to have a government franchised and supported hobby for middle-class white men we've got to find a way to justify our use of billions of dollars in public resources. We've got to come up with some solid reasons why the rich and the poor, and the other 99.5% of the middle-class, should fund our fun.

Please advise.

Wayne Hates CW!

Our CW religious fundamentalists will accuse me of hating CW. I don't hate it. I don't love it either. Do I have any other choices? Yes, I'm opposed to using a code test to keep people out of the hobby. We don't demand a typing test for new hams so we know they'll be adept at RTTY and packet and not have to sit there staring at their keyboard, trying to find the letter they want. We don't even ask newcomers to pass a spelling test.

CW is a fun mode and should be kept that. Those of us who enjoy batting out our conversations with a key should do it because it's fun. Instead we've made the code the biggest ogre keeping people out of the hobby. That's one way to make absolutely sure that few newcomers enjoy the code.

When I first started going to hamfests they all had code copying contests, complete with certificates. I'll always remember W2ECL, the local code champ, winning the contest at the Hudson Division Convention in 1938. He slaughtered 'em. I'll bet we can make it a matter of pride to be good at code by running competitions at hamfests and conventions.

One-Class License!

Other than giving up your ability to be overbearing toward those lower license classes, what have you against opening all of our bands to all classes of license?

What I'd like to see is a license issued by ham clubs to members who've demonstrated their knowledge of our rules, who have an understanding of

the various modes available to us, and who have shown they know how to operate. You want to be a ham? Join a club and get some training.

Just as important would be the right of the club to take the license away if the member they endorsed does bad things. We make it far too difficult to de-license our crazies. A ham license is not a right, it's a privilege, and it should be able to be taken away as easily as it's given. Make sense?

I'd rather see clubs handling these problems instead of lawyers and the courts.

CW Again

I got a letter from a nervous nelly who was afraid of appearing in print. It said, "I wish you'd quit picking on all us old CW operators! I've been a ham since I was 15 and still love CW and work it 90% of the time. My time on the air is half rag-chewing and half DXing, mostly on a band you don't like, 30 meters." My answer: Dear Nervous, as far as CW is concerned, I'll be even more supportive of it when you stop insisting on jamming it down everyone's throat just because you enjoy it. CW is a fun aspect of the hobby and should not be used as a weapon to keep out 90% of the kids we might attract out of the hobby. CW is fun, but it's like playing with antique cars in that it's a hundred-year-old technology and it's pathetically outdated.

Japan Has 1.3 Million Hams!

Not bad for a country with half our population. Now, if you think the ham bands are crowded here in America,

wait'll you get anywhere near Japan! It's no wonder that they are leading the world in UHF pioneering. It's really amazing to look through the Japanese *CQ Ham Radio* and see all the fantastic experimenting and building they are doing. That's probably one of the reasons their electronics parts business is still going strong, while ours is long-gone unless you hit that mother of all junk piles, the Dayton Hamvention flea market.

When you visit Tokyo, if you're a ham you'll be heading for the fabled Akihabara section of town, where endless small shops are teeming with youngsters shopping for parts. It's even better than the old Cortlandt Street (NYC) shops, where I spent much of my youth... and my allowance.

Japan is going bananas over mobile radios. They had 5 million transmitters licensed in 1989, and have been increasing about a million a year since then.

The World Direction Finding Championship

185 hams from 23 countries gathered in Siofok, Hungary, last September to participate in the 6th World ARDF Championship contest. No, no one was there from the U.S. They did have participants from all over Europe and even from Japan, China, and Mongolia! It's pretty sorry that we Americans couldn't even field one crummy team for a world championship ham contest like that. I guess our clubs are too busy with business meetings to promote amateur radio as a sport.

- Packet Radio - Portable & Affordable!

Model BP-1
Packet Modem
Made in U.S.A.

- ★ Simple Installation
- ★ No External Power
- ★ Smart Dog™ Timer
- ★ Perfect For Portable
- ★ Assembled & Tested
- ★ VHF, UHF, HF (10M)

Whether you're an experienced packeteer or a newcomer wanting to explore packet for the first time, this is what you've been waiting for! Thanks to a breakthrough in digital signal processing, we have developed a tiny, full-featured, packet modem at an unprecedented low price. The BayPac Model BP-1 transforms your PC-compatible computer into a powerful Packet TNC, capable of supporting sophisticated features like digipeating, file transfers, and remote terminal access. NOW is the time for YOU to join the **PACKET REVOLUTION!**

ANY RIG—ANY ANTENNA AUTOMATICALLY SMARTTUNER™

Let's get frank about HF antennas. Most hams try to put resonant antennas up for every band. For those with the room, great! But for the rest of us, limited to perhaps a single long wire or some other compromise antenna, the SGC SMARTTUNER is the ideal solution. Its onboard computer selects exactly the right inductance and capacitance from more than one half million possible combinations. Then it remembers the setting so your rig will retune in 10 milliseconds. It's waterproof, too, built to withstand

A Dozen New Countries Announced!

DXers Have Group Nervous Breakdown

You're going to like my sneaky plan for generating a whole bunch of new countries. Could eventually be dozens. Real new countries, too. How do I think these things up? And this brainstorm has the added benefit of not only generating billions of dollars in new business, but also saving the U.S. a bundle.

Let me start from the beginning and show you how this whole concept developed. It all had to do with the increasing pleas for the U.S. to support the disintegrating situation in Russia. Being a conservative and an entrepreneur, I'm a natural enemy of socialism and communism, so I'm not a big fan of giving money away. I'm in favor of the "teaching 'em how to fish" approach.

Financing Russia

Russia, to no one's surprise, is in one hell of a mess. Yes, it's a self-brought-on mess, so we're not terribly inclined to ante up now that they're passing the hat. Just look at the misery and expense the USSR caused the world over the last 50 years!

So here we are at a time when our Congress has already borrowed to the hilt to pay off lobbyists' demands for pork and entitlements. It's a really terrible time to see Yeltsin, tin cup in hand, begging to feed his starving family.

Russia, and the other ex-Soviet republics, are in awful shape. They haven't the infrastructure, the legal system, the banking system, or even a political system to help them cope with what's happening. Worse, the mess in Yugoslavia could well be just the beginning of a whole series of tribal wars.

I had an opportunity to go over to Russia and The Ukraine last year with a University of Virginia group to help teach them more about capitalism and entrepreneurialism. But without roads, communications, power, a business-oriented legal system, food distribution, and so on, I didn't see how I could really help much. The team, on their return, confirmed my suspicions.

Well, you've got plenty of sources for in-depth recitals of the problems facing the Soviet Republics. I've found *Foreign Affairs* particularly helpful, plus articles in *Forbes*, *Fortune*, the news magazines, and *The Public Interest*.

Yes, I've visited Russia. And the Ukraine.

Since the collapse of the USSR we're the only world superpower, which has for some reason been translated in many minds into America being responsible for solving all of the problems of the world. Not just those which pose threats to us, but those which pose threats to anyone. Methinks I detect another liberal agenda . . . another "let's tax everyone and spend the money to do a social good." And never mind that the recipients will probably end up hating us for it. We've never had much success with buying friendship.

Buying Things Instead of Friendship

A few years ago there was a call by the Russian ambassador for proposed

solutions to the problems facing the USSR as communism collapsed and they were facing massive changes. I remember sending a letter with my proposal for solving their problems. I felt that the single most critical need for all the new republics was a stable currency. Russia, for instance, needed to make the ruble convertible. To do that they needed to back it with something which had acknowledged value. They'd already plundered much of their gold hoard, so there wasn't nearly enough gold left to back their currency. Worse, to meet the demands for military, bureaucratic, and state-owned business payrolls, the printing presses were cranking out tons of ever more worthless rubles.

I pointed out that the Soviet republics did have one very solid asset which could be used to back their currencies. The governments own almost everything . . . the land, homes, factories, the railroads, and so on. If the ruble, for instance, could be backed by the real value of these assets, it could become convertible. The value pledged would have to be internationally accepted for it to work.

Thus, if the government of a republic wanted to keep the ruble presses running, they'd have to pledge more and more of their assets to back the new notes. This eventually would have a chilling effect on the normal bureaucratic tendency to ignore inflation.

This would set the stage to make it possible for foreign aid to be sent in exchange for assets instead of mere gifts . . . loans, they're called. I know I'd feel a lot better about American loans to foreign countries if I knew we were getting something of value in return . . . something more than hate. At least then, when we pour more billions into the Swiss bank accounts of third world tyrants, we'd end up owning something.

But what about that inflation business? If we "buy" land at \$50 an acre in return for lending money to a tyrant, what happens when the value of the land drops to \$5 an acre? Unk screwed again? Nope, if we get good value for our "loans" we could care less how badly they inflate their currency. The property we get in exchange will hold its value.

So Why Can't They Just Take It Back?

The assets they're exchanging for "loans" will only be recoverable if they repay the loans . . . plus interest and the value of any improvements we've made, and with inflation factored in. What I have in mind is the actual ownership of any real estate or other property by the United States or any other loaning country, for that matter. This property would be ceded to us and thus be a part of America and not be subject to their laws or expropriation. Yes, this is a tough bargain, but if they want to borrow money we need to have some real security to guarantee its return (with interest), or something of real value in exchange. And none of this 99-year lease business which has come to haunt Britain in Hong Kong.

We sure could use some land for American military and business outposts in the countries we have been giving billions of dollars to. We'd also have to be granted access via air, sea, and land to our enclaves. Make sense? And each of these enclaves would obviously count as a new country.

The alternative of not getting out

money is always there for the countries to choose.

Again, my perspective is from that of capitalism instead of socialism. The socialist impulse, which is so strong at times, is to take from the rich and give to the poor. Never mind why the people you're taking it from are rich or why the people you're giving it to are poor. Never mind that the poor spurned education, while the rich worked their asses off to be educated and then to be successful in their work.

It turns out that there are very few well-educated poor (other than teachers), and few uneducated rich. Teachers and bureaucrats, who tend to think in socialist terms, with disappointingly few exceptions, have their own self-made hell.

The capitalist approach is a quid-pro-quo. If you want money from me, what'll you give me for it? This approach could put a whole new spin on our incredibly generous loans to the socialist country of Israel. And don't you wish we'd ended up with more than a fleeting sneer of gratitude for our investment in Kuwait? As I've pointed out in the past, gratitude is one of the least felt and most transient of all human emotions. Isn't there a platitude about never lending money to friends? Well, it turns out that we never seem to.

I'd love to see an American enclave in Jordan in return for the billions we poured into that country. Hell, we'd own most of the south end of Israel by now if we'd bargained, and we'd be able to build our own settlements. We might even be able to open some schools and educate the Palestinian kids to beyond the rock-throwing stage of human development. On the other hand, we could have exported our dreadful public school system and made their situation even worse.

It's too late in the century to call this 20th century imperialism. We might call it 21st century capitalism. Just look at the success of Hong Kong, which is a good example of what I have in mind. And look at the mess they're in now that the colony is about to be returned to China. Another good example is Singapore. And Macau.

If we'd thought of this approach a few years ago we could by now own both Aqaba (Jordan) and Eilat (Israel), and have a prospering capitalist enclave on the Arabian Sea. This would have come in very handy when we wanted to cut Saddam off from the flood of food and munitions being imported through Aqaba and trucked to Iraq. I've personally seen the endless truck convoys involved in that operation.

And instead of just flat out giving aims to Egypt we could have expanded the Aqaba-Eilat enclave on down the Sinai Peninsula, making another Hong Kong or Singapore type of settlement.

So what have we now to show for the billions we've poured into Africa, Asia and the Middle East? Bupkis. All we've got is a bunch of people who owe us far beyond anything repayable, and who hate our guts. Am I exaggerating?

The next time Congress or the President get the itch to give away money let's try to talk them into getting something of value in return. Let's get them to think of investing instead of giving. This isn't a bad concept here at home the next time our liberals want to throw money at social problems. Let's consider how we can get something in exchange.

For instance, I've recommended that kids borrow money (with interest) to pay for their educations . . . starting from at least the first grade. They'll be a lot more careful in how they invest it and not be as likely to fritter their investment away. The same goes for unemployment payments and welfare. Instead of taking the money away from us in payroll deductions before we're unemployed, making us all feel as though this money is coming to us, suppose we made the payments as loans to the unemployed which would then have to be repaid from future earnings? Once repaid, the money would no longer be deducted from their paychecks.

But what about deadbeats? Their checks could start getting smaller when their total payments got out over a certain percentage of their most recent annual salary. Beyond that they'd have to report for work and do something. This crew could help keep streets clean, help in hospitals and nursing homes, and so on. We're not short of jobs that need doing that don't take a lot of education or experience.

You probably share the same feeling I do. When I eat out I'm paying for that roll and butter, so I eat it . . . even if I'm dieting and would never eat it at home. It's difficult to turn down something that you've paid for because it seems like it is free.

Hmmm, I seem to be getting off on a sidetrack again. But a good one. If Congress would insist on getting something of value in return for foreign loans there would be fewer of them and we'd at least end up with something in exchange for the taxes the IRS takes from us at gunpoint. We might even be able to make good money with our investments in overseas enclaves and thus eventually be able to cut our taxes.

No, I'm not promoting 21st century imperialism. It's capitalism. Mercantilism. I don't see why any enclaves we get in exchange for loans would have to be run from Washington. They would not be conquered territory. They'd be bought and paid for. And, as we add value to the territories, their buying back would be more expensive for the selling country . . . which would be built into our purchase agreement. We don't need to see our investments expropriated by new tyrant-run or socialist governments.

Britain had similar arrangements with Hong Kong, Sarawak, Brunei, Sabah, Australia, and other countries . . . all of which I've visited . . . so I've seen firsthand how well this protective umbrella has worked.

So let's get busy and let our Congress know we're opposed to the old style of foreign aid giveaways. Let's stop just giving and making enemies. Let's use our help as a way to spread capitalism. That will, in turn, tend to spread democracy.

If Russia is in desperate need of a bailout, and if we really can afford to go deeper in debt to help them, let's find out what we can get in return. Someplace where we can start sewing capitalist seeds in an enclave that used to be Russian. How about a couple thousand or so acres up around Yvborg, on the Baltic Sea, not far from Helsinki and St. Petersburg? That would be a great spot for a capitalist enclave, and it would tend to help the Russians in their conversion to capitalism. I'll start packing a rig to put it on the air.

Now, what other countries are in that line for U.S. handouts?

GLEN MARTIN ENGINEERING

Glen Martin Engineering has announced the addition of two new roof towers to its aluminum antenna support line. The premier model is the RT-936, a 9-foot four-leg tower capable of mounting up to 28 square feet of wind load. This tower weighs just 78 pounds and the price is \$378.75.

The lighter model is the RT-832, weighing only 37 pounds. This four-leg tower stands 8 feet tall, and will support wind loads of up to eight square feet. This tower is priced at \$189.95.

Both towers are UPS shippable. Both come complete with rotator mounting supports and a top plate stamped for direct thrust bearing bolt-up. The towers are constructed of rugged 6061-T6 angle aluminum with stainless steel hardware.

For more information, contact Glen Martin Engineering, Route 3, Box 322, Boonville MO 65233; (816) 882-2734, FAX (816) 882-7200. Or circle Reader Service No. 202.

ANTENNA SALES & ACCESSORIES

ASA has introduced a new HF mobile antenna package for the enthusiast: Model HFA-COM (High Frequency Antenna Combination). This package consists of five separate frequency "fiberwhips": 10, 15, 20, 40, and 75 meters. The unique design of these fiberwhips eliminates the need for retuning after each breakdown and set-up. The antenna is designed to withstand a heavy wind load with solid brass and chrome-plated hardware to handle the elements. The approximate assembled length is eight feet. It is priced at \$65, plus \$5. S & H. For more information contact ASA, P.O. Box 3461, Myrtle Beach SC 29578; (800) 722-2681. Or circle Reader Service No. 206.

AMATEUR NETWORKING SUPPLY

Amateur Networking Supply has introduced two new products designed especially for packet network builders: the Netrix Diode Matrix Board and the WireModem Adapter.

The Netrix is used to create a network switching node of up to six TNCs. The unique stacking configuration eliminates the need for cables, offers significant performance advantages such as higher speed and reliability, costs less than similar products, and is compatible with all TNCs.

The WireModem Adapter is an inex-

pensive yet reliable plug-in circuit that connects up to six TNCs together via their modem disconnect headers, using a passive WireLan matrix. Applications include connecting multiple network switching nodes together, hardwiring a data server into the network,

TEN-TEC

TEN-TEC has introduced a miniature HF transceiver priced at \$495. Simply plug in the desired band module and run SSB or CW on any ham band from 160 through 10 meters. Measuring only 2.5" x 7.25" x 9.75" and weighing five pounds, it is about half the size of many small HF transceivers. This 50 watt travel companion truly fits in a briefcase with room to spare. A patented Jones filter provides variable bandwidth 9-pole crystal filtering from 500 Hz to 2.5

kHz. A built-in microprocessor keeps the VFO virtually drift-free and handles the built-in iambic keyer. For more information contact TEN-TEC, Inc., P.O. Box 8010, Sevierville TN 37864; (615) 453-7172, FAX (615) 428-4483. Or circle Reader Service No. 203.

ADVANCED ELECTRONIC APPLICATIONS

For antenna enthusiasts everywhere, the new AEA SWR-121 handheld antenna analyzer provides comprehensive antenna performance information in an easy-to-read graphic format. With its LCD spectrum display, the SWR-121 shows an antenna's SWR curve over an entire frequency range, unlike other instruments which can look at only one frequency at a time. This battery-operated unit is designed for portability and easy use.

For more information, contact Advanced Electronic Applications, Inc., P.O. Box C2160, 2006 196th St. SW, Lynnwood WA 98036; Sales: (206) 774-5554, literature request line: (800) 432-8873. Or circle Reader Service No. 201.

DIGITAL COMMUNICATIONS

DIGITAL Communications Inc. has introduced a new voice mail system for repeaters, consisting of the DCI-100 computer board and the DCI-MULTIM-BX multi-user mailbox software. The board plugs into your IBM PC or clone and connects to your radio or repeater. Individual messages are recorded by one user for replay by another. They are recorded on your hard disk in individual mailboxes for replay at a later time. The only limit on the number of

users or messages is the size of the hard disk. You can store roughly an hour's worth of messages for every 20 Mb of free disk space. The DCI-100 board is priced at \$199 and the DCI-MULTIMBX software is priced at \$60. For further information contact DIGITAL Communications Inc., 8946 Shook Road, R.R. #4, Mission, B.C., Canada V2V 5M2; (604) 820-1162, FAX (604) 826-0704. Or circle Reader Service No. 204.

or creating a gateway between different network types. The WireModem can operate at 19,200 baud or more.

Both products are compatible with ROSE and TheNET networks. For

prices and more information contact Amateur Networking Supply, P.O. Box 219, Montvale NJ 07645; (201) 573-2717. Or circle Reader Service No. 205.

David Cassidy N1GPH

Not That Anybody Asked Me, But...

... We had a great time at the Dallas hamfest this past June. I'll take Dallas over Dayton any day.

... Now that the Novice license testing falls under the VE program, how long do you think it will take for the Novice license to go the way of the dinosaur? Also, how many hundreds of youngsters living in non-urban areas will say "ah, screw it" when they find out they have to convince Mom or Dad to drive them a hundred miles or more for a license test?

... Why do volunteer examiners get to charge a fee? I thought this was a hobby. Let's see, if you have 25 people show up for an exam session, and they each give you five bucks, you'd walk home with a little over \$40 in your pocket (assuming that you split the total among the three VEs). Not bad for an hour's work.

... I hear that the new software being installed at the FCC licensing facility in Gettysburg has provisions for assigning special call signs for a fee. I hope Congress lets the FCC keep the money they collect for issuing custom call signs.

... Our sister publication, *Radio Fun*, achieved something unheard of in the publishing world. A "renewal percentage" is the number of renewals a magazine gets every month, compared to the number of people whose subscriptions expire in that month. Anything over 70% is considered excellent (73 consistently has a renewal percentage of around 80%). In February, *Radio Fun* had approximately 3500 expirations, and only 3 subscribers didn't renew. That's close enough to call it a renewal percentage of 100%. It's gratifying to know how much the readers of *Radio Fun* love their magazine.

... We had a nice 6 meter opening on the East Coast last week. From my shack in New Hampshire (using an antenna cut for 10 meters), I heard stations in Virginia and South Carolina. I was on the phone with Gordon West yesterday (he lives on the West Coast) and while we were chatting his 2 meter radio started receiving the beacon from Hawaii. Ah, doncha' just love summer band conditions!

... Why is it so difficult to get people to have a real conversation on the ham bands? We have got to stop this "three-minute monologue then give your call sign" type of QSO. You don't do that with your buddies on the local repeater, so why do we all turn into Edward R. Murrow when we get on HF?

... I've got my 20 meter portable QRP station all set for my summer camping trips.

... Could you guys on 20 meter CW slow down a little? I haven't worked a whole lot of CW lately, and I'm a little rusty.

... Does anyone out there know how to keep deer from eating your tomatoes? Last year, I started about 30 tomato plants from seed, in my kitchen window, in the middle of February. I babied those little plants and had enough plum tomatoes ripening by August to last us all winter (if you've never made tomato sauce with fresh garden tomatoes, you don't know what you're missing). I didn't think the deer would eat tomatoes. Boy, was I wrong! I went away to the National Convention last year, and when I got back, there wasn't a single tomato left.

I've got three dozen tomato plants of

several different varieties growing in my garden this year, and short of building a fence, I can't think of anything that will keep the vermin from dining on the fruits of my labor. Send your gardening tips to me, c/o 73.

... Could you guys on 20 meter CW please slow down just a little bit more? I'm rustier than I thought.

... Would anyone out there like to trade some ham gear for an ultralight vehicle or small plane? Send your inquiries to "The Poor Pilot", c/o 73.

... Speaking of aviation, if you're into flying and are at all interested in the areas of experimental, homebuilts, kilplanes or ultralights, you really ought to be reading *Kilplanes* magazine. The publication is extremely well done, and the head honcho is a ham!

... Why do some of you insist on sending mail to my home address? If you want to respond to me in my capacity of Associate Publisher of this magazine, please write to me at the magazine. It really irks me when I get business mail at home (and I never answer it).

... President Clinton still hasn't found anyone to head up the FCC. The woman he was rumored to have chosen has withdrawn herself from consideration, so as of this writing it's anybody's guess.

... As I'm writing this, President Clinton is having a chat with shuttle astronauts. He just mentioned the SAREX program! Hey, maybe we should get Chelsea's school signed up for the next SAREX mission. Just think of the positive publicity for amateur radio.

... I'd like to get into ATV.

... Speaking of ATV, I hear that there is a move afoot to change the rules so ATVs could broadcast music as part of an ATV transmission. I'm not so sure this is a good idea. What do you think?

... Ummm, you guys on 20 meter CW—just a little slower and I think I'll be all set.

... Have you checked out America On-Line yet? If you're using Prodigy, you'll be amazed at how fast a real online service can be. AOL doesn't mind "for sale" messages, doesn't censor like Prodigy does, doesn't force you to read ads, doesn't charge extra for downloading software, allows you access to Internet e-mail, and it has live conference areas, so you can communicate in real time with a whole bunch of people about any topic under the sun. There's a great ham radio area, too. My AOL address is "D Cass." If you check it out, send me a note.

... Watch for Wayne Green's re-entry into the computer publishing field—coming to a newsstand near you this summer.

... Wayne's other new magazine, *The Secret Guide To Music*, is growing like gangbusters! If you're a corporate music slave, you probably wouldn't be interested, but if you are the adventurous type and would like to find out about thousands of independent recordings, you really should check it out. They can be reached at the same address as 73.

... I love to run into 73 and *Radio Fun* readers on the air. Look for me on Saturday and Sunday mornings on the 40 and 17 meter bands (10 meters, too, when it's open). You can always send a message via packet to N1GPH@WA1WOK.NH.

... OK—you guys on 20 meter CW—just a little slower—please. 73

Jim Gray W1XU

Jim Gray W1XU

Payson AZ 85541

Just when you thought the lousy July conditions were going to end, you find out the first days of August are probably going to be worse! However, from about the 5th through the 18th, it looks like conditions will be Fair or Fair to Good, with the better days from about the 14th to the 18th. Unfortunately, the days between the 19th and 24th are expected to be Poor or Very Poor, but improving slowly, so that the days between about the 25th and the 31st will be vastly improved, compared to the previous week.

I expect the ionosphere to be greatly disturbed and the earth's magnetic field to be at the major storm level sometime between the 20th and 23rd.

In general, August is a "blah" month for HF propagation, but normally conditions improve as September and the fall equinox approach. Bear in mind that we are now dealing with low to moderate solar activity as Cycle 22 rapidly nears its 11-year minimum.

10-12 Meters

There will be reasonable openings on north-south paths occasionally during the afternoon hours. Sometimes there will be F2 openings to Pacific spots and rare ones to Europe early in the day during the days marked Good on your chart. Short skip 1,300-2,300 miles.

15-17 Meters

Regular DX openings are expected on days marked Good and are expected in the Southern Hemisphere during daytime hours, especially in the afternoon. Expect occasional openings on east-west paths to Europe or Africa on days marked Fair to Good, with rare excellent conditions to all parts of the world on a few days. Short skip 1,000-2,000 miles.

20 Meters

This is probably your best bet for worldwide DX on Good days, with the band opening from sunrise to a bit after sunset locally. Early mornings and late afternoons provide peak conditions. Short skip will range from about 750 miles to 2,000 miles frequently.

30-40 Meters

On Good days, expect openings from after dark to local sunrise to most parts of the world. Expect daylight short skip from 100 miles to 1,000 miles and beyond 1,000 miles after dark.

80-160 Meters

Openings will occur on some days during darkness hours and again around sunrise on Good days. Expect frequent trans-equatorial skip 100-1,000 miles during the day (if we're lucky) and beyond 1,000 miles after dark. Noise is abating from summertime levels. On 160 meters, conditions peak after midnight and again just before dawn. This is the best "night-owl" band for those who are able to take advantage of it. No openings are expected during the day, however, but during darkness hours, you'll work short skip out to 1,000 miles and more. 73

NEVER SAY DIE

Wayne Green W2NSD/1

Vox Pops

A letter from Richard KC4YQL got me to thinking. Now, you know that's gonna make trouble. And sure enough, trouble it is. But I think you're going to like it, if you're just a bit anti-establishmentarian. As an admitted proponent of disestablishmentarianism, I hope you go for it.

Richard made the usual mistake of coming up with a good idea and proposing it to the ARRL. Now you'll find no one more enthusiastic and supportive of the wonderful works being done by our esteemed League than your semi-humble servant. But, even in my unabashed admiration for the Newington Marvel, I do occasionally admit to some of the very slightest of misgivings about their bureaucracy and inertia, which in rare instances can give one the impression we're trying to deal with a federal agency. I'm always saddened when the true worshippers of our Radio Relayers blow my slightest of criticisms totally out of proportion, often subjecting me to outrageous vilification and slander. But that's in the same vein as Rushdie's problem with the equally religiously obsessed ayatollahs of Iran.

That aside, let's get down to brass tacks. No, I can't put that all aside yet. Sorry. But Richard's proposal has a lot to do with what a few malcontents perceive as a weakness on the part of the League. Heresy, of course, but these things have to be faced and resolved. It has to do with the false perception that the League's Board of Directors is far more involved with carrying messages from headquarters to the unwashed than in carrying the wishes of the unwashed to those high on Olympus . . . known locally as Newington.

Why not, begged Richard, let us lowly members comment on proposed rule changes before a firm position is taken before the FCC? Well, of course we old-time members know that we always have the right to write and express our opinions to HQ. Of course, I can't recall any instance, at least in the 50 or so years I've been a member, when these comments were taken into consideration. But that may be due to the admittedly faulty memory of a doddering old-timer who is gradually slipping into the pre-senility stage. That's what happens when one retires and

has too much time on one's hands.

But I happen to like the basic idea. In fact, why not take this one step further? Instead of coming up with good (and bad) ideas for rule changes and then dropping the ball . . . or far worse, sending them to the FCC . . . how about our starting a Vox Pops section in 73 where your proposals can be exposed for the brilliance or the stupidity they represent? We'd print 'em and the readers would then have an opportunity to congratulate you for your brilliance or vent their spleens over your incredible ignorance. The end result would be a reader poll. Those with enough support would be forwarded to the FCC for action and the rest would be given at least a decent burial.

Now, I know this whole concept is going to give the ARRL Board members fits. Only the League is supposed to interface with the FCC. All of us hams are supposed to first get the ARRL to agree with our proposals and then let them take it from there. Alas, the League's past record on reflecting the actual wishes of the members hasn't been exemplary, tending more to represent the interests of the Directors and those we've elevated via the Board to Olympus. I still vaguely remember the many years I fought the ARRL to get FSK permitted below 2m. They put up one hell of a battle, but they eventually lost.

The League, bless them, seems firmly rooted in the past. CW, that fascinating artifact from the 19th century, is obsessive. Many of us are eagerly awaiting a carbon dating report on test equipment discovered in the ARRL lab.

So, if you have some ideas for rule changes that you think are important, let's send them up for some flak from our inexhaustible supply of negative old-timers, who are against almost any changes, no matter how needed. If, after the smoke clears, the readers give a thumbs up vote, we'll submit your gem to the Commission and cross our collective fingers. How's that play for you?

So let's see some samples of your genius coming in to Vox Pops, 73 *Amateur Radio Today*, Peterborough NH 03458-1107. Maybe we can get this confounded hobby into usable shape yet.

Calling All Entrepreneurs

A note from Al Warsh N6UHF brought an article in the April *Mensa Bulletin* to my attention. It had to do with the need for a better avalanche beacon transmitter for skiers who get their jollies skiing in avalanche-prone areas. It seems that the current crop of such devices left enough to be desired so no one was able to locate a chap (or his body) who was in the wrong place at the wrong time last winter.

My advice is to take up downhill skiing and try to stay on the trails. This has been my approach and it's worked perfectly for me in 25 years of skiing. Yes, I know it's more expensive . . . unless you're my age and can ski free most places . . . but it is safer and more exciting. Oh, I tried cross-country skiing. Bor-ing. I haven't seen my cross-country skis, boots, and collection of waxes recently, so some past employee is probably enjoying them. Or has sold them.

If you're into experimenting, you might want to see what you can do. You want to find out what the current crop of beacons do, so you can do much better. I wish I'd saved some of the snow from last winter to help you experiment. We had plenty along in March. You need to find out what frequencies can get through about six feet of snow and for what range. Then you have to package the transmitter so it doesn't take a dog-sled to cart the power supply.

Once you have a nice small package and a manufacturing facility, if you don't have the money to finance the project you then have to find a venture capital outfit that will fleece you of everything in short order. They'll move the manufacturing to Taiwan, where copy-cat firms will clone the product, quickly putting the venture capital firm out of business. You'll end up with the comforting knowledge that it's your invention that's selling to millions of cross-country skiers through Eastern Mountain Sports and other ski outfitters.

While on the topic of entrepreneurialism, several readers of my book, *Declare War*, have mentioned that they've found it a gold mine of entrepreneurial ideas. Of course, I can't help coming up with more and more ideas for ways to make money. If you've bought the

book perhaps it's time to sit down and start reading it. But then you probably have your ear plugs screwed in tightly so as not to be annoyed by knocks on the door by Opportunity. Well, it's a lot easier to buy lottery tickets than to work, anyway. Unfortunately, the only number of yours that's likely to come up will be that one on your ARRL Silent Key certificate. I'm not sure if you have to be a member to get that award or not. Better join, just in case, right?

Gloom and Doom Revisited

Is technology about to eliminate the major excuse for amateur radio's existence? We've been buffeted by technological developments ever since WWII. First there was the transistor, a new-fangled contraption most old-timers never really quite got used to. And if that wasn't bad enough, then they began cramming parts on boards instead of on a chassis. Worse, then they shrunk the boards and transistors down to quarter-inch-square integrated circuits. By this time most hams had bailed out.

If we'd kept kids coming into the hobby we might have bridged the gap. Kids, not having been brought up on tubes, resistors, tuning capacitors and output transformers, were comfy with gates and phase-locked-loops. Alas, we zapped the kids in 1964 and they've never really come back.

So here we are in the '90s, with synthesized HTs and TNCs, and for most of us not a clue as to what's going on inside our predominantly black boxes. CW was replaced in the real world a generation ago by high-speed digital communications systems and facsimile. Now, when our rigs break, we don't get out a soldering iron, we get out the shipping box and call UPS.

No longer are we a technically educated resource for use in time of war. No longer are we inventing and pioneering new technologies as we did 50 years ago. We're not even doing much of value as good will ambassadors. Our one remaining claim to our billions of dollars in publicly-owned frequencies is our ability to provide emergency communications.

Some of our clubs are doing a fine job of this. They're outfitting emergency vans and have emergency-powered repeaters either in place or ready to set up. They're set to help different services intercommunicate. And they're able to provide short-, medium- and long-range communications by virtue of our many ham bands. Now, I admit it's true that most of our emergency communications systems are as slow as Gettysburg and prone to endless errors. Many of them are still rooted in the glorious 1930s, using CW and voice. But we do have a growing number of more modern systems using packet, digipeaters and networks. We have a few hams who are doing their best to set up these faster systems, despite endless interference from the officials of a national ham organization which I won't mention, for fear of being accused of trashing them, Iorsooth.

Continued on page 74

From the Hamshack

Rickey Nievera N2MBC, Carle Place NY Wayne, keep up the good work. I wonder if you will change the makeup of 73 Magazine to less kit building and more about ham radio operations, hints, kinks and the like? How about a "sermon" on how we can rebuild the "image" of hams: stopping the chaos on 20 meters, encouraging more activity in public service, volunteering in schools and in Boy Scout programs? Hams should be good citizens and not enemies of their neighborhoods because of TVI. Good neighbor relations should be stressed. Hams need to read more about preventing TVI, RFI, and telephone interference, and should ease up on power amplifiers during popular TV hours and on weekends. The rule is if you have a good contact (at least 5/7) there is no need to use a linear amplifier. Give the hams on low power a chance to get on the air. The guys with big console linears wipe the rest of us out. It's not fair! At least 80% of us use no more than 100 watts. The culprits are the Extra Class hams. Come on—let's get together and behave. Follow the rules and regulations. Let's have less bull-shit talk on the ham bands. No politics. Let's talk about technical items, computers and the like. Please—no politics over ham radio.

I have been a ham for over 25 years, as DU1EN, and now as N2MBC. I enjoy DX, not hearing about the country's problems and so forth. I usually hear some hams that I know from way back and we rag-chew about the old times. That is ham radio—friendship, learning about geography, etc., not too much foolish talk. Let's all enjoy this hobby—it is a great one—and not spoil it.

You're probably right, Rickey, We should not be discussing politics or religion over the air. As Arnold Glasgow said, "The fewer the facts, the stronger the opinion," so arguments about religion, where facts are nonexistent, are fruitless. And political arguments seem to seldom be based on any firmer ground, so let's avoid talking about the deficit, unemployment, welfare, racism, our lousy school system, crime, drugs, the recession, Congressional pork and bribes, Clinton, Rodham, Perot, and other such political matters. Why am I reminded of The Pirates of Penzance, where the chorus sings, "Let us compromise, (our hearts are not made of leather). Let us shut our eyes, and talk about the weather. Yes, yes, let's talk about the weather. How beautifully blue the sky, the glass is rising very high, continue fine I hope it may, and yet it rained but yesterday. Tomorrow it may pour

again (I hear the country wants some rain), yet people say, I know not why, that we shall have a warm July." . . . Wayne

Michael Graham, Baton Rouge LA I am writing in response to Jeff Carter KK6RY's letter (July 1993) as I await the arrival of my call sign from the FCC after having successfully completed the no-code Tech exam. I've read Carter's letter a number of times, becoming angrier each time. He seems to have some horrible need to feel superior to somebody, and has apparently directed his pseudo-superiority attitude toward the no-code Techs, who he feels will turn the 2 meter and 70 cm bands into some not-so-glorified channels resembling CB. Perhaps he has a poor concept of human nature. An exam demonstrating a degree of knowledge must be taken and passed. CBers just aren't going to do that. They haven't in the past, they don't now, and they're not likely to expend that energy in the future.

The no-code route into amateur radio was, I believe, designed to bring into the fold people like me—educated, reasonably intelligent, and who possess some knowledge of computers. I can't, of course, speak for all no-code Techs, but personally I'm already reading and learning, and eventually will achieve Extra Class. Carter's attitude toward us is the kind of elitism that cannot help but damage efforts to promote amateur radio.

I am angrier when Carter writes, "Let the no-coders run the local bicycle races and show off with their \$500 handie-talkies." Carter apparently has no use for public service. It's called giving something back. It's called serving your community. Baton Rouge just finished hosting the National Senior Olympics—successful in large measure due to the efforts of many amateur operators using a 2 meter repeater, their skills in communication, and a whole lot of their personal time.

I regret that Carter feels superior to me, and that I'm not good enough for him. If I run across his call on the air in the future, he'll not have to worry about wasting time communicating with me. I'll be too busy talking with people who care.

Clyde D. Nimal N8YBK, Columbus OH The letter by Jeff Carter in your July 1993 issue really burned me up. It is obvious to me that he doesn't know what he is talking about.

I have been licensed twice: once under the "old" system, where knowing the code was mandatory, and again under the new system.

While I felt that the old system was harder to work with, it did maintain a certain technical edge and launch many an electronics career, mine among them. I had little difficulty learning the code and eventually got a General Class ticket. But I remember well one poor chap who struggled mightily just to be able to tell the difference between a dit and a dah. For him, being tone deaf, this was a mountain to climb, not a hurdle to jump. To him, the present system would have been a godsend. I cannot help but wonder how many other potential hams we lost due to this one barrier.

It is equally obvious that because Mr. Carter has opted to not use VHF anymore, that he is missing out on a fact that makes his whole argument moot. There are quite a few of those "handie-talkie appliance operators" learning Morse code and upgrading. Every one of them has a no-code license, and one of them is hearing impaired! As one of the net control operators of the local CW practice net, I am well aware of the desire of these newcomers to upgrade and get on the HF bands.

Overall, I think that amateur radio will survive quite well with this new generation of hams, code or no code.

Steven L. Sanders N4WAK, Clearwater FL Wayne—I just finished reading your editorial in the June 1993 issue—sure am glad that I'm only an Advanced Class and not an Extra! You're always mentioning the 14,313 mess and I think that it is time to recognize another frequency as being possibly the second-worst for intentional interference . . . 14,230. I am an avid SSTV and am constantly amazed at the amount of amateurs who persist in using 14,230 as the national tune-up frequency, even when there are at least four or five stations actively talking or sending SSTV images that anyone with a piece of wire for an antenna would hear (if they listened first).

You also solicited comments from those of us who have purchased a new piece of equipment on what we have gone through getting it to operational condition. I have always leaned towards the purchase of ICOM gear, both for VHF/UHF and HF, and have recently purchased a new ICOM IC-W21AT dual-band handie. The radio is excellent and operates as well as the IC-W2A that it replaced. It takes awhile to learn all the bells and whistles even though it has an "AI" button for those of us who need some artificial intelligence.

I am very happy to see that companies like W & W Associates have come out with "universal" chargers that are capable of being fitted with a reasonably priced adapter so it can be used with a variety of radios. One of my major gripes over the last couple of years has been the ridiculous cost of a rapid charger for amateur handie-talkies. I mean, come on, get serious . . . you can buy a 9.6 volt

rechargeable drill with a battery pack and a quick charger for around \$50 at any hardware store, so why does an amateur charger have to cost so much? You always hear the old song and dance about how small the amateur community is versus any other consumer base and how they have to charge more, etc. I think they know that most people who buy an HT will also buy a rapid charger (for obvious reasons) and it's just their way of showing us how much they appreciate taking our hard-earned money.

I want to thank you for the articles you have published in the last year or so dealing with amateur slow-scan TV. The number of people on 14,230 and 14,233 using the SSTV mode has increased faster in the last year than in all of its previous years. Now, if we can just educate the rest of the amateurs out there and make them realize that we need a good 5 kHz of band above and below these two frequencies it would be great. We voluntarily constrain ourselves to operating SSTV and FAX modes on just these two frequencies on 20m and we could just as easily go anywhere and do it but we don't—we respect the rest of the ham population. Hopefully, we will soon be using advanced digital modes for transmitting images and possibly linking the sending and receiving stations and using error-correction, but right now it's more like RTTY than AMTOR.

Good luck and keep on fighting! I don't always agree with everything you say in your editorials but I never fail to come away thinking, "What if he's right?" Glad to see someone always taking shots at the ARRL, they need someone to snap at their heels and keep them (somewhat) in line!

Ed Campbell KD4SMQ, Macon GA As a new no-code ham, I subscribe to several magazines, including 73. When you asked for information on how we liked our new equipment, I thought I'd write with my experience.

Like many new hams, my first radio choice was an HT. Nothing gets you "on the air" as quickly or as cheaply. I purchased a Standard 168 and really love it. It is very well-built; I have even dropped it onto a concrete floor with no damage. At home I connect it to an attic antenna and power supply. I also use it with a mobile mag mount, but often I just carry it in the car with the rubber duck and hit the local repeater just fine.

I am working on the 5 wpm code to obtain my Tech Plus, but I must admit that it is not much fun and I often wonder, "What's the point?" Unless you can copy 13 wpm, there is little HF voice available to the new ham.

Question: With all the new no-code hams out there, why don't the manufacturers produce 6 meter rigs? a 2m/6m dual-band mobile would interest me.

Thank you for your magazine. How about some articles on 6m fun? **73**

Nervous Habit

The Associated Press reports the mystery of an electrician's lead poisoning was solved when the man revealed he enjoyed chewing bits of plastic coating he stripped off wires. A routine blood test indicated 48-year-old Elmer Galbraith, who lives near Johnstown, Ohio, suffered 10 times the normal lead level for humans.

Galbraith knew something was wrong when he sensed a tingling in his fingers and began suffering from memory loss and diminished math skills. The unusual case was documented in a government report which issued a warning about the hazards of chewing plastics which may contain lead. *TNX A.P./Scott Schram KN4L.*

Windy City Scanners Safe

Members of the Chicago Area Radio Monitoring Association are breathing a collective sigh of relief after waging a successful battle against the Chicago Scanner Bill. Jon Peterson N9OUM contacted this publication back in July when he found out members of the Chicago Board of Aldermen had proposed passing an ordinance which would have made owning a scanner a crime.

The names and addresses of these aldermen and details of their proposal spread like wildfire to computer bulletin boards across the country—including the 73 BBS. Jon reports that the response was impressive enough to cause the Chi-town leadership to do an about-face on the issue. The revised ordinance proposal punishes only those individuals who use scanners to commit crimes or interfere with police. A pat on the back for those who wrote letters. *TNX N9OUM/The Chicago Area Radio Monitoring Association.*

Mega-Telescope

The largest single integrated astronomical instrument in the world formally entered service on August 20, when the Very Long Baseline Array (VLBA) was dedicated at ceremonies in New Mexico. The continent-wide radio telescope system is the culmination of a half-century of development in radio astronomy.

The VLBA offers scientists the most detailed views of celestial objects available from any telescope on earth or in space. With 10 receiving stations distributed across 5,000 miles of US territory, its radio vision is sharp enough to read a newspaper in New York from the distance of Los Angeles.

To make images of astronomical objects, the VLBA uses ultra-sensitive radio receivers, superfast tape recorders, atomic clocks accurate to within one second in a million years,

and a high-performance computer that can perform 750 billion computations per second. The project is funded by the National Science Foundation. *TNX National Radio Astronomy Observatory.*

Quick Charger Extends Battery Life

A small Austrian company—*Enstore R&D GmbH in Graz*—has come along with a quick charging technology which not only does not harm batteries, but may actually extend their usable lifespan. A new chip is used to monitor the state of the battery's charge during the recharging process. Doing so allows the charger to feed the battery as much current as it can handle without causing heating or gassing.

The Enstore electrode-specific charging system (ECS) is touted as the solution for the dreaded memory effect suffered by NiCd batteries. Enstore claims the ECS can extend the useful life of a NiCd battery to 5,000 charge-discharge cycles from a typical average of 500 cycles. Application for the new technology is likely to spread from small hand-held electronic devices to electric cars. *TNX The Institute of Electrical and Electronics Engineers: The Institute Vol. 17, July/August, 1993.*

WACO Hams

At least two licensed amateur radio operators are now believed to be among those killed in the Branch Davidian Compound fire near Waco, Texas, on April 19. The FBI has identified Jeffrey C. Little and Douglas W. Martin as being among the followers of cult leader David Koresh who perished after the compound was set ablaze.

Koresh is believed to have set fire to the compound rather than surrender to the FBI after a prolonged armed standoff. Little AB5KZ and Martin AB5LA had both upgraded to Amateur Extra Class on February 23rd of this year. *TNX Westlink Report, June 25, 1993.*

Ticket Time

The FCC's enforcement division has been busy lately. Three Los Angeles area amateur radio equipment dealers have received Notices of Apparent Liability (NALs) in the amount of \$7,000 each for marketing the Kenwood TS-50S HF Transceiver which could be "... operated on frequencies not authorized for amateur radio use." The complaint apparently stems from a brochure which originally mentioned the rig's ability to operate above and below the ham bands.

This brochure has since been reprinted showing only the rig's ham band capabilities.

Four out-of-band CB operators are being fined from \$2,000 to \$3,500 each for their infractions. A fat \$10,000 fine has been levied against Lonnie N. Gwinn of Federal Heights, CO, for selling external CB RF power amplifiers at a truck stop.

Margaret G. Taylor of Windermere, FL, was told she owed the government \$2,000 for her unlicensed amateur radio operation.

Four computer companies were ordered to cough up from \$7,000 to \$10,000 each for marketing personal computers which did not have the proper FCC equipment approvals.

The Southern Railway Company was fined \$7,000 for refusing to allow an FCC inspection of their radio base station. *TNX W5YI Report, Issue #14, July 15, 1993.*

CQ Taxi!

The New York City Taxi and Limousine Commission has decided to ban the use of ham radio as a means of communications for Big Apple cabbies. The measure prohibits the permanent installation of amateur transceivers or accessories in NYC Medallion taxicabs.

The ruling was an apparent response to a bid by a trio of New York City drivers to equip every cab in Metropolis with ham radio. Local repeater groups joined the influential trade publication *Driver* in opposition to the proposal.

Drivers may still carry low power handhelds for personal communications during off duty times outside the cabs, but they must be turned off and kept out of sight while the taxi is in service. *TNX Westlink Report, No. 652, June 25, 1993.*

Israeli Hamsat Launch

The Israel Polytechnical Institute will launch its first satellite known as the *Gerwin-1* (formerly *Techsat-1*) from the Baikonur spaceport in Kazakhstan aboard a Russian rocket. Professor Guiora Shaviv, Director of the Space Research Department, said the satellite will weigh about 60 kg and will carry a packet BBS for ham radio operations.

The satellite from "Technicon," as the institute is known throughout the world, was a project which began three years ago and will be placed in orbit as a secondary payload along with a Russian satellite and a German satellite. *TNX Westlink Report No. 652, June 25, 1993.*

. . . to all our contributors!

Computer Control for Beam Antennas, Part 2

Completing the project.

by Ron Cole K4OND

In Part 1 we reviewed how antenna rotators work, how to build a simple manual rotator control, and how to get a position readout in electrical form. We can now proceed to the ultimate—complete computerized control of azimuth and/or elevation. With a little hardware and software, you can implement a system which can automatically track a moving “target” (i.e., a satellite), automatically turn to the correct azimuth for a DX location or a selected repeater, or simply have fun using a

joystick to control something as big as an antenna. The discussion below assumes you are using an IBM PC or clone computer. If you have some other type of computer, you will still get some useful ideas, but you will have to design your own hardware interface and software.

First, let's look at how your computer can control one or more rotators, how it “knows” where your antennas are pointing, and finally, how to put the system all together.

Computer Interface

Somehow, we first have to get usable signals out of the computer. Although you could build your own interface unit (if you know enough about the internal workings of a PC), a quicker and easier way would be to buy a kit made for this purpose. JDR Microdevices (2233 Samaritan Dr., San Jose CA 95124) sells several such kits, or you can buy a completely wired and tested board from them. The JDR PCL-720 (\$169.95) is a

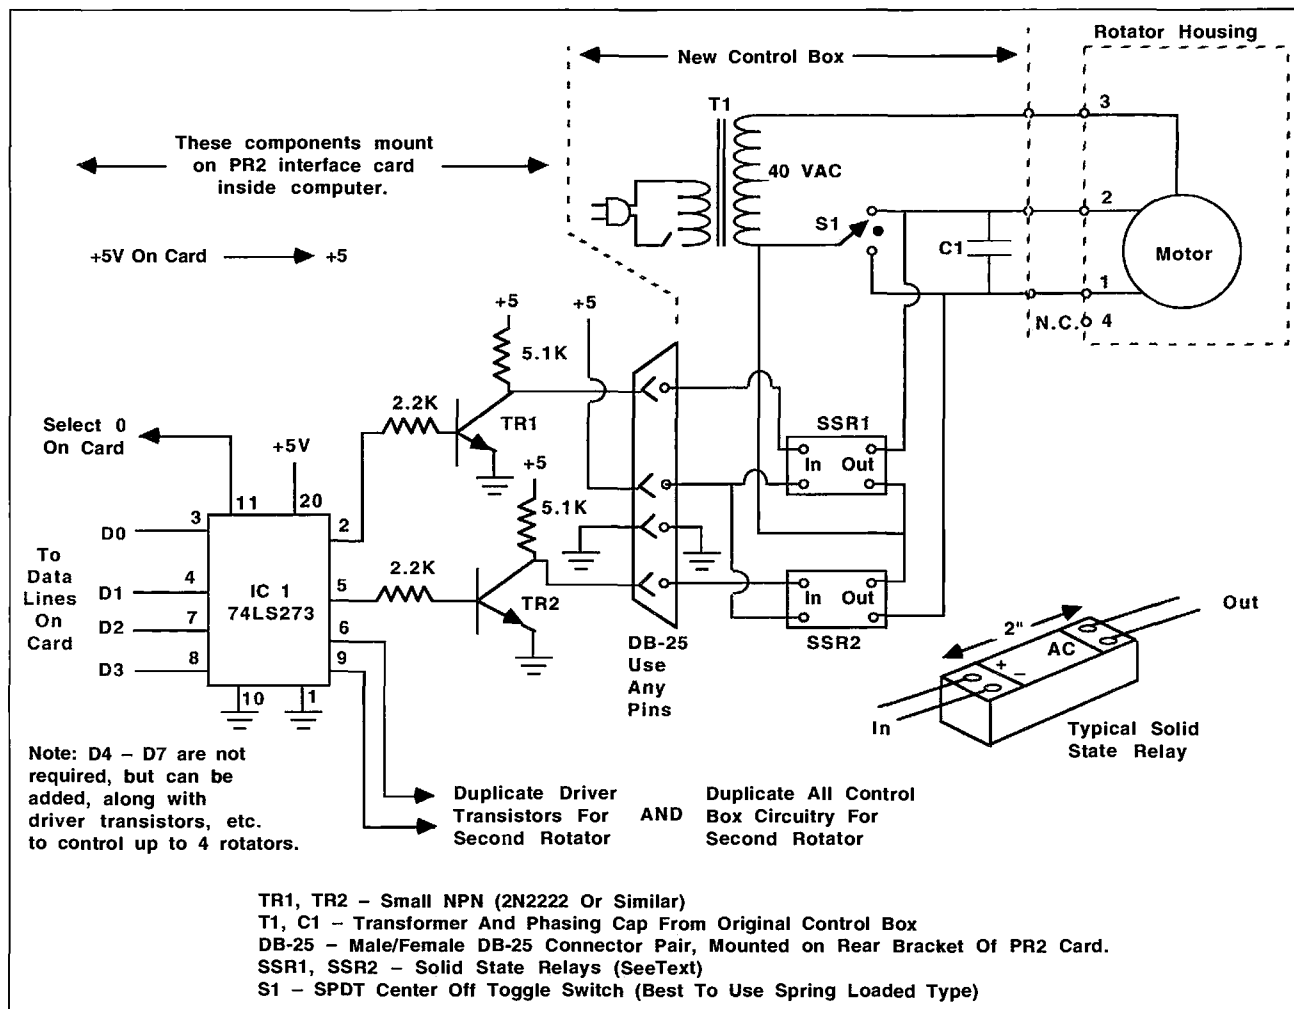

Figure 1. Computer control of rotators.

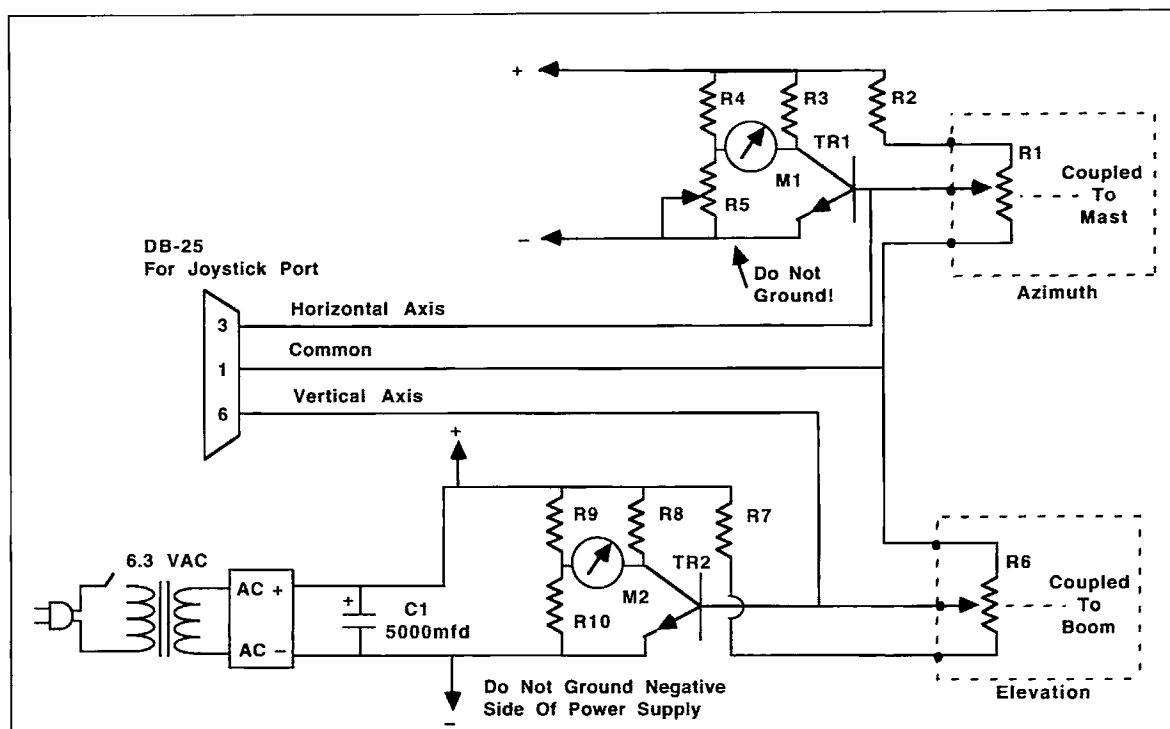

Figure 2. Using joystick port.

fully-assembled I/O card which has more than enough input and output channels for several other projects besides a rotator control. That card also includes three timer/counter channels which you may find useful, and some software drivers written in BASIC. I bought the JDR-PR2 "prototyping" kit (\$29.95), and the PR2-PK parts kit

(\$8.95) instead, and added the additional circuits and parts. Assembling my board took only about an hour, and it worked immediately upon installing it into a spare expansion slot on the motherboard. The instructions with the kit are quite clear, and JDR includes several suggestions for other projects using the board.

What the PR2 kit gives you is "decoding" of a block of input and output addresses; that is, it gives you the ability to send data to, or get data from, external devices by appropriate software commands. The PR2 kit actually gives you the ability to address up to 32 separate data ports, many more than you will need in our controller. It also has plenty of

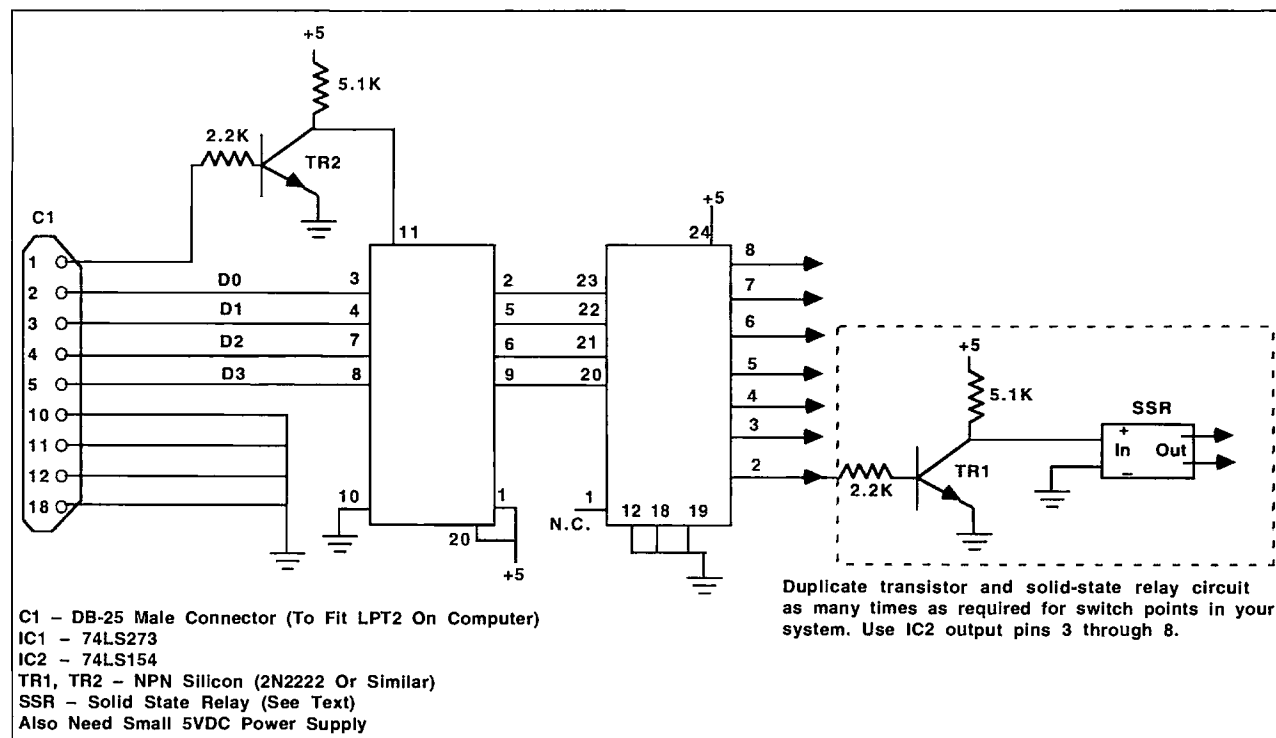

Figure 3. Quick and dirty interface.

room for the handful of ICs and transistors we will need.

A DIP switch which comes with the kit allows you to select the range of addresses for the ports. With switch 1 off (up) and the other three switches on, the address range will be from 768 to 799. As supplied, and without any further decoding, the PR2 actually decodes "blocks" of four addresses each: to make full use of all 32 addresses, you will have to add more decoders. However, for our purposes, we only need one port address. Let's decide to use address 768 for that port.

If you are familiar with the BASIC computer language, you probably recognize the software command "OUT x,n" which sends a number, n, (which must be between 0 and 255), to whatever device is connected to the data port at address "x." We need to have something at the data port to capture and store the data word, then operate a relay which will control the rotator. The "something" we need is an 8-bit data latch, the 74LS273 shown as IC1 in Figure 1. When the computer executes the "OUT 768,n" command, the 8 bits of data (whatever we send for "n") will come out on the data bus while a single "write strobe" pulse appears on the output line which has been decoded for address 768 (that is, the "Select 0" line in the case of the PR2 interface board). The write strobe latches the data into IC1.

For a little extra protection of the computer against accidents (since we are about to connect to the "harsh" external world), the output pins of IC1 are routed first to a set of driver transistors. In turn, the driver transistor outputs are routed to a DB-25 connector, which mounts on a bracket supplied with the PR2 kit. From the connector, a cable connects to our new control box, which contains the "solid-state relays." SSR1 and SSR2. (A "solid-state relay" is an integrated package specially designed for interfacing logic-level signals to high power levels in the real world. They require only about 3 volts on the input to operate, and at current levels easily provided by small transistors. They are much too large to fit on the interface board inside the computer, but we don't want them inside anyway, since they are going to be switching some voltages and currents, which could mean instant death to any other computer chips. (Note that if you want to test these relays, you must have a large AC voltage on the output side or they will not seem to work; you cannot test them with just an ohmmeter.)

We next wire the outputs of the solid-state relays in parallel with the manual switch (S1) described in Part 1 of this article. SSR1 applies our 40 VAC motor power to one side of the phasing capacitor to produce rotation in one direction, while SSR2 can apply power to the other side to rotate in the other di-

rection. When neither relay is on, no power is applied, and the rotator stops. If you wire the circuit exactly as shown in Figure 1, you can control the rotator with just three BASIC commands: OUT 768,1 causes rotation in one direction, OUT 768,2 rotates the other way, and OUT 768,0 stops all rotation. If you want to control a second rotator (i.e., for both azimuth and elevation) you will have to add two more driver transistors connected to IC1, two more wires down to the control box, and duplicate the transformer, phasing capacitor, solid-state relays, etc., in the control box. When wired to the data latch as shown, BASIC commands for the second rotator would be "OUT 768,4" for one direction, and "OUT 768,8" for the other direction, and, again, "OUT 768,0" to stop. (Unless you understand binary arithmetic, be a little careful of sending any other commands to port 768, since some data words will try to make a rotator turn in both directions at once! If you do understand the binary values involved, you can figure out how to control both rotators at once, but remember that the stop command (OUT 768,0) will stop both rotators, even if one of them needs to keep going longer.

Now that we have one or two rotators under computer control, let's see how the computer can determine where the antennas are pointing. Although the more elegant method would be to use a separate "analog-to-digi-

“The R8 is a like a breath of fresh air, with its ground-up engineering and up-to-date digital control from the front panel... a quality HF receiver of American manufacture that should successfully compete on the world market.”

Bill Clarke
73 Amateur Radio Today

“Overall, the Drake R8 is simply the best radio we have ever tested for quality listening to programs... There's nothing else quite like it.”

Lawrence Magne
Monitoring Times

“The best of the best for high-quality listening to news, music and entertainment from afar. Superb for reception of faint, tough signals.”

Editor's Choice
Passport to World Band Radio
Tabletop Receivers for 1992

WHAT IN THE WORLD ARE YOU LISTENING TO?

The world is an ever-changing place, but there is one thing you can rely on to remain the same...the Drake reputation for American-crafted, quality communications products and unsurpassed customer service. Now, the Drake R8 Worldband Communications Receiver has been heralded by the experts as "the best of the best," delivering "unparalleled all-around listening performance" that is "right up there with the best for DXing."

So if you want to keep up with a changing world, and you're not listening to a Drake R8, we'd like to suggest you make a change. Call 1-800-723-4639 today for more information about the R8, to find the dealer nearest you, or to order an R8 direct from the factory with a free 15-day trial period. If you're not impressed by Drake's quality, performance and ease of operation, all in a receiver costing less than \$1,000.00, return the R8 Receiver within 15 days, and we'll refund your money in full, less our original shipping charge.

The world is a big place. If you want to hear it all, listen to a Drake R8. If you're missing it, what in the world are you listening to?

A Quick and Dirty Interface

There is a sneaky way to achieve computer control of rotators which eliminates the requirement for building or buying an interface card, and requires almost no external hardware, but it depends on your familiarity with BASIC programming and your willingness to do some experimenting. First of all, you need a second line printer (parallel) port in your computer; it should be set up as printer port "LPT2." If you don't already have one, you can get an interface card for about \$20. The parallel printer port can be made to act very much like the output ports we created with the interface board described earlier. However, instead of sending data to an output port ("OUT 768,n", etc.), we are going to "LPRINT" the data to LPT2. External to the computer, we have to build a data latching circuit using a 74LS273 just as before. Then we will use a 74LS154 4-line-to-16-line decoder IC to interpret the data and activate

one of 16 output lines to cause rotator action. (One and only one of the 74LS154 output lines will go to the low level for each value of "n" between 0 and 15.) The low level outputs are routed to driver transistors, then to solid-state relays as before. Figure 3 gives the basic concept.

The quick and dirty way to get position readout depends on software only. It turns out that you can get a fairly accurate estimate of the antenna position by simply starting from a known point, then computing how many times you have to go around a software loop to use up enough time to rotate to the new position. That is, for example, if the antenna is known to be on an azimuth of 35 degrees, and you want to turn to 77 degrees, you can develop an algorithm which tells you that it takes "x" seconds to rotate 42 degrees. Then you start the rotation, go around a software loop ("FOR I = 1 TO n: NEXT I")

to create a time delay which is "x" seconds long, then stop the rotation. You will have to do some experimenting to find out what kinds of "x" and "n" values you need; these are highly dependent on your computer's speed and how fast your rotator actually turns. Be sure to include code in your program to save the most recent heading(s) for the next use, because the computer doesn't have any idea where the antenna is really pointing! (Engineers call this an "open loop" control system because there is no feedback from the thing being controlled.) You also need to save the last heading(s) to a data file before you turn the system off, and reload the file the next time you turn it on. Remember, also, that with this "quickest and dirtiest" method, you will have to run your antenna control program every time you want to move the antenna or see where it is pointing.

tal" convertor circuit, the easiest way to get into the computer is to connect the potentiometers into a "joystick" (or "game") port. Joysticks are nothing more than a pair of potentiometers, anyway. My system uses a game interface card made by Gravis. This card expects to see a joystick which has potentiometers of about 100k ohms each. The connections for the joystick port are shown in Figure 2. (Since most joysticks built for use with PC clones are interchangeable, the pin connections should be the same for any game card, but you should check by testing a joystick known to work with your comput-

er.) Note that one side of the potentiometers is common, but that the common line is not grounded, and you need to make sure your potentiometers are not grounded somewhere.

Unfortunately, that's not quite all there is to it. Back in Part 1 we used the rotator potentiometer to drive a meter circuit to display position, and this required applying a small voltage to the potentiometer. If you're like me, you want to retain that meter readout capability (along with the direction control switch, S1) so that you don't always have to run the computer. However, with

that voltage applied to the potentiometer, we cannot now simply hook the potentiometer directly to the joystick port because the game card expects to see a pure resistance only, not a voltage or current.

Figure 2 shows a way to simultaneously drive a meter and a joystick port from the same potentiometer. One side and the wiper of the potentiometer control the base current in an NPN transistor, which is one leg of a bridge circuit. The meter provides the manual-visual display. The other end of the potentiometer and the wiper are used as the input to the joystick port. Note that the transistor

MODEL 1450S
HPA

All amplifiers (non-rpt) are linear, all-mode with fully automatic T/R switching and PTT capability. The receive preamps use GaAs FET devices rated at .5 dB NF with +18 dBm 3rd order IP. LPA, Standard and HPA amps are intermittent duty design suitable for base and mobile operation. Repeater amps are continuous duty, class C.

Amplifier capabilities: High-power, narrow or wideband; 100-200 MHz, 225-400 MHz, 1-2 GHz, Military (28V), Commercial, etc. — consult factory. A complete line of Rx preamps also available.

```

and meter portion of the circuit use a "floating" power supply—the negative side of the supply must not be grounded or you can accidentally ground one side of your joystick, with possible damage to the game card. In this application, you need to use a rotator potentiometer (R1) of about 100k ohms since the game card expects such a value in the normal joystick application. Also, pick a linear-taper potentiometer for R1, again to emulate the joystick.

I have also used one other method to get both a meter display and a joystick port driver. That method involves putting an LED diode in the collector circuit of the transistor, and optically coupling the LED to a cadmium-sulfide photoresistor (Radio Shack 276-1657). The CdS photoresistor has a "dark" resistance of at least 100k ohms, and can go down to less than 100 ohms with just the light from an LED. The CdS photoresistor can then be connected directly to the joystick input lines. With this method, there is no electrical path between the meter circuit and the computer, only a safe optical coupling. I assembled the LED and photoresistor unit by inserting the devices into opposite ends of a 1/2" piece of heat shrink tubing. Even after shrinking, enough light leaked in that I had to cover the whole unit in black electrical tape. (Do not try using a "phototransistor" for this purpose; they just don't seem to work, but the CdS cells work fine.)

If you are going to use either of these methods, be prepared to do some amount of juggling of the values of components in the circuit. The hardest part of all is to find a set of components which will produce a linear scale on the meter (that is, without having half of the antenna movement squeezed into one-fourth of the meter scale, etc.). On the joystick side, true linearity is less important since we have to build a look-up table in the software to translate "joystick" values to azimuth and elevation angles anyway.

And Just for Fun . . .

If you have at least one joystick port still

available, and a joystick, it is really easy to control your antenna with it (and fun to steer something as big as an antenna with a joystick!) Let's assume that the horizontal pot on your joystick appears as "STICK(0)" in BASIC, and the vertical pot appears as "STICK(1)," and that the STICK values are 50 when the joystick is centered. Let's further assume that you used output port 768, with OUT 768,1 meaning rotate clockwise, OUT 768,2 meaning rotate counter-clockwise, OUT 768,4 meaning rotate up, and OUT 768,8 meaning down. Then the "joystick" part of your BASIC program could look something like that shown in the list at left. You need to add more code to break out of the infinite loop of the program, and to display the position as the antenna moves.

All Together Now

Software is the "glue" which sticks the system together. Now that you have the ability to start and stop rotator(s), control their direction, and get computer feedback on antenna position, you can do almost anything you want via software. If you can write programs in BASIC, the preceding discussions are probably as much as you need to put together a working program. If not, a sample package is available from the 73 BBS (603-924-9343) or address (ppn 70310.775) on CompuServe. For \$5, a blank (formatted) disk, and a suitable (padded) SASE, I will also send you a package which includes programs for building your own look-up tables, automated heading menus, graphical (compass) displays, "quick and dirty" timing algorithms, etc., with lots of textual explanations (address: HC 69 Box 1150, Moncks Corner SC 29461). Most programs will be in BASIC, but some have also been compiled to run under DOS. What I don't have (yet), is a program which tracks satellites from ephemeris data, then feeds the real-time position information to an antenna control program for complete autotrack. I would love to hear from anybody who knows of a good tracker, available in BASIC, which can be merged with a controller program.

Parts Availability Notes

JDR Microdevices, 2233 Samaritan Dr, San Jose CA 95124, sells cards for PC clone interfacing. The general-purpose "Prototyping" I/O used in this article is the "PR2" card (\$29.95). It is a "full-size" board, plugging into an empty "8-bit" slot on the motherboard. The PR2 has printed wiring for address decoding, saving a lot of time. Save more time by getting the PR2-PK parts kit. (\$8.95) Good instructions come with the kit, along with a complete schematic.

All Electronics Corp. (P.O. Box 567, Van Nuys CA 91408; 800-826-5432) usually carries solid-state relays. If not, try Digi-Key (701 Brooks Ave. South, P.O. Box 677, Thief River Falls MN 56701-0677; 800-344-4539) or Surplus Sales of Nebraska (1502 Jones St., Omaha NE 68102; 402-346-4750).

Radio Shack has almost everything else you will need, except maybe the 74LS273 ICs, but these are carried by most parts houses, including Digi-Key.

The W2EKY "Icky-Stick" Antenna

Hit the roof with an improved ground-plane vertical.

by Ronald B. Koester W2EKY

I lost virtually my whole shack in a fire, and purchasing a replacement rig left me little cash for an antenna or antenna tuner. My first inclination was to put up the proverbial dipole, which usually requires tree climbing (me chicken) or the tools used by Robin Hood. I opted for neither.

My favorite band is 15 meters. This band, combined with the slope of my new shack, made the situation right for a ground-plane antenna. But any connoisseur of antenna theory knows a vertical antenna is only as good as its counterpoise. The traditional ground plane with the usual four drooping radials has a performance only about equal to that of a vertical dipole.

Being an old fan of cubical quads and their broad bandwidth, I decided to use two quad loops in place of four radials to try to improve overall performance, laying the loops on each side of the roof. I used 14-gauge plastic-covered wire, but you can try using whatever happens to be in your junk box.

The wire loop corners can be secured with nails or hooks (see Figure 1). The Icky-Stick is fed with RG 58/U or RG8/U. Using 21.3 MHz as the design center, the height calculates to be:

$$H_{\text{feet}} = \frac{246}{\text{Freq. MHz}} = 11 \text{ feet } 6 \text{ inches.}$$

Each loop length is calculated by:

$$L_{\text{feet}} = \frac{1005}{\text{Freq. MHz}}$$

= approximately 47 feet.

Construction

The antenna is constructed of two pieces of 3/4-inch (i.d.) aluminum electrical conduit, a 2-foot piece of 1-inch (i.d.) PVC plastic pipe, a 3-foot tripod and #14 wire.

The first section of conduit is cut to a length of 5 feet and is joined with the upper section with a pipe union (usually supplied with conduit). This allows the upper section to be easily removed and pruned (great fun in a high wind) for the lowest SWR. The lower section is drilled to accept 2-10/24 brass machine screws and nuts 1 inch in length (see Figure 2). Secure the loops with soldering lugs and wing nuts.

Figure 3. The W2EKY (Icky-Stick) Antenna.

Figure 1. Ground plane detail.

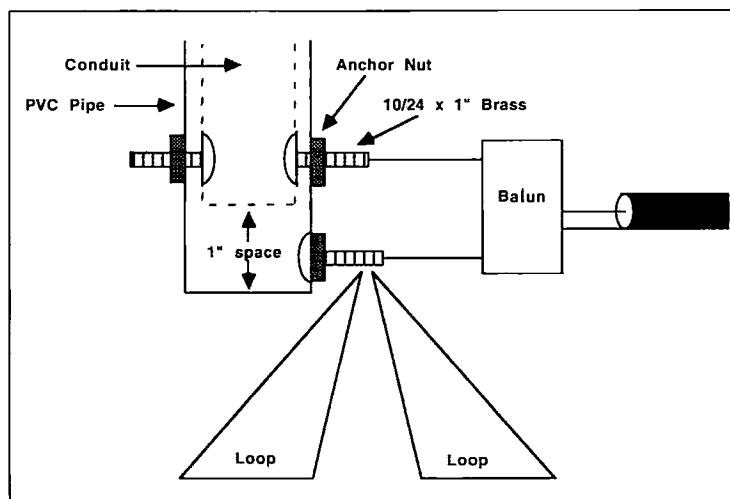

Figure 2. Antenna base detail.

The bottom of the radiator is insulated from the tripod by the 2 feet of PVC pipe. Unfortunately, the PVC pipe does not slip over the conduit unless it is split along its entire length. This is easily accomplished with a radial arm saw or bench saw.

After spraying the first 2 feet of the bottom conduit with WD-40, tap the PVC pipe on. Make sure that a 1-inch space is left between the bottom of the conduit and PVC. This space allows for connecting the balun transformer and loops. I suggest that you use soldering lugs on the wires.

"All the signals I could hear I could work, and with strength equal to or better than that received."

Performance

All the signals I could hear I could work, and with strength equal to or better than that received. It appears that the vertical pattern is at a lower angle due to the loop counterpoises. Interestingly, the Icky-Stick showed a low SWR across the entire band. I also attribute this to the loops. I recommend that the coaxial cable be fed *between the loops*, as I did note some interaction at this QTH. Although the Icky-Stick can be fed directly with coaxial cable, I strongly recommend that a 1:1 balun be used. Without the balun there is a strong chance of TVI and pattern skewing.

As with any vertical, antenna gain would increase if the length of the radiator were increased to 1/2 or 5/8 wavelength. This, of course, would require the use of guy wires (uh-oh).

Happy DX!

73

Compressing the W3EDP

Build this unique multiband restricted space antenna.

by Richard Q. Marris G2BZQ

The W3EDP antenna first appeared around 1936. It was, at that time, an unorthodox multiband antenna design, in as much as it consisted of an 84-foot end-fed wire plus a 17-foot counterpoise, and no ground connection. It was usable on the 80, 40, 20, and 10 meter bands using the same 17-foot counterpoise, except that on 20 meters 6-1/2 feet was suggested. Some people also used it on the 160 meter band. The whole thing was resonated by a coil "L" and variable capacitor "C" (see Figure 1). The coupling coil was connected to the TX output with feedline. Various explanations have been offered over the years as to how the design was arrived at, and how it works, but the truth seems to be that this multiband antenna and counterpoise lengths were originally arrived at by lengthy "cut and try" experiments.

From time to time over the years the W3EDP has "raised its head" in a textbook or magazine and then disappeared again for a few more years. During recent years the W3EDP seems to have proved quite popular among the QRP folk in Europe.

It seemed, to the writer, that if the W3EDP could be really shortened (or compressed) it would make a very useful restricted space antenna for the 80 meter band, and experiments along these lines were carried out, every time keeping the 17 feet counterpoise.

The most obvious idea was to make a

helical version about eight feet long, mounted horizontally. With a helical antenna, a "rule of thumb" method is to wind twice the normal length of wire on an insulated rod or tube, and prune down to resonance by removing a few turns at a time. Therefore, 175 feet of wire was wound around a piece of 1-inch o.d. PVC tubing. Using a 17-foot counterpoise, turns were gradually removed until all the 80 meter band could be tuned using L and C, as in the full-size W3EDP. The contraption

"With the final design, it was possible to work throughout Western and Eastern Europe using CW between 3500 and 3600 kHz and about 10 watts CW."

worked, but was very narrow bandwidth, and C had to be retuned every few kHz. So a non-helical approach, to compress the antenna, was investigated, with the result being a 30-inch diameter end-fed spiral arrangement (see Figure 2). A further improvement in coupling and bandwidth was made by tapping the coaxial feedline onto L in lieu of the original coupling coil. The antenna was tested mounted both vertically and horizontally. Vertical gave the best results.

Using about 10 watts CW, with the new antenna standing on a coffee table in the

middle of the room, and with the 17-foot counterpoise lying on the floor, it performed very satisfactorily. The construction was modified so that the spiral winding was halfway between the ceiling and floor. About 16 feet of RG58 feedline went to the TX via an existing "T" match ATU, located alongside the TX/RX. This ATU eliminated all TVI, which had been slightly present when the feedline went direct to the TX output.

With the final design, it was possible to work throughout Western and Eastern Europe using CW between 3500 and 3600 kHz and about 10 watts CW. (The antenna will cover the whole of the 3.5 MHz band.)

Once adjusted, the variable capacitor C was "locked" as it was not necessary to retune it. The counterpoise length was changed +/-, but 17 feet gave the best matching and results, as per the original W3EDP. Furthermore, the counterpoise, made of well insulated wire, could be laid either straight, zig-zag, or in "L" or "U" shapes on the floor, with no noticeable change in performance.

Construction

The antenna consists of a 30-inch diameter end-fed spiral winding, wound on an octagonal shape timber mainframe (see Figure 4). The mainframe (see Figure 3) consists of four lengths of timber, each 30" x 5/8" x 1/4". A hole is drilled in the center of each, and glue is applied around the

Figure 1. The W3EDP.

Figure 2. The compressed W3EDP.

Figure 3. Mainframe construction.

Figure 4. Winding detail.

holes on each timber length. The whole is secured with a bolt, nut and washers. The timber "radial spokes" are arranged in the configuration shown in Figure 3, then the nut and bolt are securely tightened to hold the "spokes" in position while the glue is hardening.

A vertical wood support 23" x 0.8" x 0.8" is screwed and glued to a 12" x 8" x 1/2" timber base, as shown in Figures 3 and 5. The fan of radial spikes is bolted to the top of the vertical support (see Figure 3). The whole mainframe assembly can now be wood-stained.

At the end of each radial spike, a standard 12-way 2 amp polythene terminal block is secured with wood screws, and a piece of Perspex sheet measuring 4" x 4" x 3/16" is mounted, as shown, with two wood screws with washers under the heads (see Figures 3 and 5). [Editor's note: Polythene is the British variation of polyethylene, and Perspex is the British trademark for a hard transparent plastic similar to Plexiglas.] The 250 pF variable capacitor C is mounted on the Perspex sheet, as shown in Figure 5.

Assuming low power operation, a good quality well-spaced receiver type variable capacitor can be used. Alternatively, a 2-

gang 500 + 500 pF variable can be wired in series. Remember that this VC is not at true ground potential, and is therefore mounted on the Perspex plate and fitted with a shaft coupler, insulated shaft, and a 3" diameter instrument knob (see Figure 5).

The B & W Miniductor coil (type 3047) is vertically mounted on a couple of small insulators. On 80 meters the whole of the coil L is connected across the variable capacitor. The coaxial feedline is tapped up from the bottom of the coil for the best coupling point. As a guide: On the prototype, and using RG58 feedline, this tap point was 7-1/2 turns, but it is well worth experimenting with the tap position for best results.

The winding of the spiral antenna, using PVC-covered stranded hook-up wire, is clearly shown in the winding detail (see Figure 4.) The turns are wound counter-clockwise through the holes in the 12-way terminal blocks. At every complete turn the terminal block grub screw should be tightened just enough to hold the wire taut before winding the next turn, and so on.

The counterpoise is the inner polythene-covered conductor removed from a length of RG58, and is clipped on at the junction of C and the bottom of L, as shown in Fig-

ures 2 and 5. The coaxial feedline should be secured to the wood base with a couple of cable cleats (see Figure 5).

Operation

Initially, the antenna should be tested with a receiver on the 80 meter band. At 3500 kHz the prototype was resonated with variable capacitor (C) plates about 50% en-meshed, and was found to give a real lively reception performance over the whole band.

Next, the antenna should be fed with a few watts from the TX. An existing "T" type ATU, adjacent to the TX, was an advantage in matching and in eliminating TVI, which was slightly present when the antenna was connected directly to the TX output. Alternative coil taps on L should be tried to achieve the best loading and lowest SWR.

Assuming that the antenna is located in the middle of the room, one resonance setting of C should suffice over 100 kHz+. At this QTH, for use between 3500 and 3600 kHz CW, C was resonated at 3550 kHz and then "locked."

Other Bands

The prototype compressed W3EDP was

Figure 5. Mounting L and C: A) front view; B) rear view; C) side view.

Figure 6. The finished product.

only required for use on the 80 meter CW band, but there seems to be no reason why it should not be used on 40, 20 and 10 meters (using a 6-1/2-foot-long counterpoise on 20 meters) as in the original W3EDP design. This could be done by tapping the coil L from the top, and moving the coaxial feedline tap. A convenient method would be to make 3-pin plug-in coils. The smaller higher frequency coils could be made of 16- or 14-gauge self-supporting tinned or silver-plated wire. Alternatively, the existing B & W coil could be switched using a ceramic switch.

There is much for the experimenter to try.

Alternative Ideas For the Experimenter

A couple of variations are worth mentioning:

1. The height of the spiral antenna winding can be increased by lengthening the vertical support section between the perspex plate and the wood base.

2. No doubt the antenna could be used in a loft, on a flat roof, or other outdoor site, and weatherizing the device would be necessary, and L and C sealed in a suitable box.

Parts List

C	250 pF variable capacitor (see text)
L	B & W Miniductor type 3047
Wire	PVC stranded hook-up wire (Radio Shack 278-1218 or similar)
Coaxial feedline	RG 58 (16 feet used on prototype)
8	12-way 2 amp polythene terminal blocks
1	Wood base 12" x 8" x 1/2"
1	Vertical wood support 23" x 0.8" x 0.8"
4	Wood spiral supports 30" x 5/8" x 1/4"
Perspex	4" x 4" x 3/16"
	3" diameter instrument knob plus 1/4" shaft coupler plus 1/4" insulated shaft (and slow motion drive, if required)

Conclusion

The compressed W3EDP prototype proved to be a very effective restricted space antenna. As a monoband 80 meter antenna, during spasmodic operating periods, it has been possible to work all over West, East, North and Southern Europe from a QTH in the south of England. Operating has been restricted to between 0415 and 0530 GMT, when conditions are not at their best. No attempt has been made to work during the nighttime DX hours—the writer has reached an age when he prefers his bed.

NEW DSP AUDIO PROCESSOR

From JPS

The new NRF-7 is a medium priced DSP product which provides great flexibility in audio processing. Modes available include atmospheric (white) noise reduction through adaptive peaking; spectral multi-tone notch filtering; notch & peak combined; wide (2100 Hz) and narrow (1500 Hz) SSB filters, with and without spectral notch; wide (500 Hz) and narrow (200 Hz) CW filters with selectable center frequency; and a 500 Hz wide

NRF-7

Only: \$249.95

The NIR-10, the standard in DSP Noise Reduction, still only \$349.95.
For eliminating carriers & other tones, the NF-60, still only \$149.95.

DATA filter centered at 2200 Hz. All filters all operate in real time, so they can be used for Break-in CW, AMTOR, PACTOR and ARQ modes. Note: noise reduction by adaptive peaking reduces noise by dynamically reducing the bandwidth and is not effective against impulse-type noise. Only the NIR-10 uses spectral subtraction to eliminate impulse noises as well as atmospheric noise, while retaining the full audio bandwidth.

Distributed Capacity Twisted Loop

An indoor 40 meter antenna for five bucks.

by Jim McLelland WA6QBU

I am one of those unfortunate hams who lives in a neighborhood which does not allow visible outdoor antennas. To make matters worse, the HF bands continue to deteriorate, and I have found it increasingly difficult to communicate after dark without a decent 40 meter antenna. Therefore, I had to find a solution: The Distributed Capacity Twisted Loop. The DCTL was designed for indoor and portable use on the lower high frequency bands. The requirements were: The antenna had to be small, cheap (less than \$5), easy to build, constructed of easy-

to-find parts, simple to adjust, and work reasonably well.

The following project constructs a flexible loop style antenna that hangs up almost anywhere (I drape it from my bookcase) and can work all over the Western U.S. and Hawaii on 40 after the higher bands have closed up. Moreover, I hear some DX and I can null out (down 30 dB) broadcast stations by rotating the DCTL on a camera tripod. It is quiet to boot! Interested? Read on! Or better yet, spend \$5 and an hour of your time and build one yourself.

Description

Referring to the schematic (Figure 1) will probably tell you all you need to know. Since this is an experimental antenna that I am continuing to adapt to different situations and bands (160 meters is in the works), many construction details are left to the builder.

The DCTL is a 15' 7" equilateral triangle made from 300 ohm TV lead-in (Radio Shack 15-1153); this is the narrower 5/16" variety. Spacing affects the dimensions so stay with this type of lead-in. The resonant frequency can be lowered by making the open stub longer. With no stub, the antenna resonates at 7.250 MHz, and with a 2" stub, it resonates at 7.050 MHz. I use a 1" stub and a tuner to go anywhere I want on the band. I also use the same low-loss twin-lead into the balun on my tuner—which I strongly recommend because the bandwidth is less than 100 kHz.

The DCTL has an impedance of 5.5 ohms and matching to 300 ohm line is accomplished with a 27-1/2" shorted stub across the feedline at the antenna. This is known as a "hairpin match" and adds some inductance to the antenna and lowers the resonant frequency. With a 50 ohm system (see "Tuning and Experimenting"), the hairpin stub is shorter and therefore the antenna requires a longer open tuning stub (capacitance) to make up for the loss in inductance.

A very important point that must not be overlooked is that the loop has a half-turn twist in it. This means that the feedline is not only connected to opposite ends of the loop but also to opposite sides. To be sure you are doing this right, use an ohmmeter to check for *no continuity* before you hook up the shorted stub and feedline. This lets the insulation act as a high quality capacitor between the antenna legs, which lowers its resonant frequency. With this system, approximately 1/8 wavelength acts like a half-wavelength system. The open stub just adds a little more capacity to the open opposite ends of the antenna so it can be tuned across the band.

Construction and Installation

To make this antenna work properly, solder all connections and insulate well with

Figure 1. The Distributed Capacity Twisted Loop 1/8 wave antenna stands five feet high.

electrical tape and shrink tubing. Measure very carefully, remembering that an extra 2" can put you clear out of the band. Hang as an equilateral triangle with the apex and feedline down, staying away from metal such as housewiring, vents, downspouts, flashing, rain gutters, and windowsills. Lastly, do not use staples to hold the thing in place. As a safety note, *remember that loops have high voltages and high currents. Therefore, don't let anyone (including dogs, cats, kids, or the XYL) touch it.* I've used it with a 100 watt rig with no smoke or sparks yet, but I'd still be very careful.

Tuning and Experimenting

If you only have an antenna tuner, balun and SWR bridge, build the DCTL as described, tune it for 1:1 SWR using low power (I fried my internal balun by not doing this), and look for a QSO. As a side note, an external balun is better than the small internal units most tuners have. Another good alternative is to put RF beads or two of the clip-on RF forms Radio Shack sells on the

coax leading to the rig. Any ground wires then go only to the rig, leaving the tuner isolated.

If you want to play a little, here's some more information: I used an MFJ Antenna Bridge for all my initial measurements. A longer open stub lowers the resonant frequency, a longer shorted stub raises the impedance and lowers the frequency, and the shape affects everything somewhat. If you want to use 50 ohm coax directly, use an open stub of 9", a shorted stub of 8-1/2", and clip 1/4" pieces off the open stub until minimum SWR is centered where you want it. You should also coil some coax at the feed point to make a balun (or use one of Radio Shack's cute little forms that I mentioned earlier, winding 10-15 turns of RG-174 on them). Actually, however, I can't tell the difference with or without the balun. Theoretically, the null point on one side of the loop disappears but there is so much pattern distortion inside a house that it really doesn't seem to make any difference. Remember that if you want to use this antenna without a

tuner, its bandwidth is only about 100 kHz. If you have a tube rig with a pi-network and a balun, it's no problem, but the new solid-state rigs are another story.

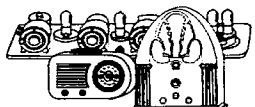

Field Tests

The first station I worked was near Seattle, about 1,000 miles away. Signals were good (7-9) on both ends and the op could hardly believe that my antenna was only 5' high. The next guy was in Salt Lake—same story. Later the same evening I worked a station in Hawaii—he kept saying, "You've got what kind of antenna?" The signals were not very strong but they were quite readable, except for the Pennsylvania station that couldn't hear either of us and kept calling CQ.

As a final note, if you can carefully rotate the antenna, you can really null out broadcast stations. While holding it over my head and rotating it (good thing nobody saw me doing this), I could reduce a 20/9 broadcast station to S7. I think I've got something here, folks.

Evolution of an Antenna

Build a new version of the classic "Lazy H" antenna.

by Sidney Rexford W2TBZ

Not much is new in the design of antennas, and most of the new can be traced to the old. After all, almost 100 years of antenna experimentation has exhausted most of the configurations imaginable. The antenna described in this article is a case in point. Basically, this antenna is a "Lazy H," a vintage workhorse which has an impeccable reputation as a stellar performer.

Let's review the old before going on to the newer version. The classic "Lazy H" is shown in Figure 1. It consisted of four half-wave radiating elements, two side by side over two more also side by side, with all four elements fed in phase. The array's gain will vary as the spacing between the upper and lower elements is varied from a half wavelength to a quarter wavelength, with the greater spacing giving slightly more gain than the lesser spacing. In practice, few hams could get sufficient height while erecting their antennas to make much more than quarter-wave spacing practical, so the evolution of this new version is based on quarter-wavelength spacing. By removing the old feed system and leaving just the radiating portions of the antenna, we find that just the four half-wave elements shown in Figure 2A will do the job.

In electrical circuits (and antennas are no exception), when two points exist with the same polarity and phase relationships, these two points can be connected together. The ends of both the upper and lower pairs of half-wavelength radiating elements fit this condition, so the ends of the lower half-wave elements can be bent up and those of the upper half-wave elements bent down to meet. They are then fastened together. This forms two loops separated by a quarter wave, as shown in Figure 2B.

Our antenna now has become two quad loops in phase and will be treated as such. It is important to realize that the end effects taken into consideration in the original "Lazy H" antenna computations to deter-

mine the length of the elements have been altered and the current formula for the overall length of the loops is now 1005 divided by the frequency in MHz. This is the standard formula used in determining the overall dimension of full-wave loops.

Obviously, the feed system used in the original "Lazy H" antenna is no longer practical to feed the new loops. The old phasing lines and the tuned feeder were located high in the air and were difficult to work with. A newer and more modern feed system is necessary. If the loops are opened in the center of the bottom of the loop, and you check the radiation resistance, you will find that it is 100 to 130 ohms, depending on height and ground conductivity under the loops. These points on the loops must be fed in phase and with equal voltages to come up with a working antenna. The most difficult part of the problem is in choosing the manner in which this is done.

A half-wavelength piece of transmission line of any type will act as a 1:1 transformer and reflect the terminating impedance at both ends, so a half-wavelength of transmission line (any transmission line) attached to the loops will appear to have an impedance equal to the impedance of the loop itself. A little experimenting with various types of lines determined that either standard 300 ohm ribbon or 450 ohm ladderline worked best. Coax was tried, but unless a 1:1 balun was used at each loop, radiation from the braid became a problem. The ribbon or ladderline was self-canceling and did not present any distortion of the antenna pattern.

A half-wavelength line from the center of each loop, brought together and fastened in parallel so that the loops are fed in phase, provides an impedance of 50 to 60 ohms, and a 50 ohm coax feed from antenna to hamshack will give an excellent match

without a tuner. To prevent radiation from the coax braid, a 1:1 balun should be used. A W2DU balun was used on this antenna. Ferrite core baluns were also used successfully. The use of air core baluns proved disappointing and they are not recommended. Construction details are shown in Figure 3, and dimensions for the loops and the phasing lines are shown in Table 1. As long as the termination (ends) of the ladderline or ribbon phasing lines are mechanically constructed so that flexing is distributed over at least a foot, the lines can be left to swing in the breeze.

This is a single-band antenna, and it is bidirectional. For the 40, 17, 20 and 15 meter bands rotation to provide full directional coverage would be a real challenge, but for 10 and 12 meters, a rotatable framework is feasible.

While the theoretical gain of this array is about 3 dB over a dipole, on-the-air results are better. The antenna is a lower angle radiator than the dipole at the same maximum height and, in the tradition of the "Lazy H," it does a fine job in DX contacts. Radiation patterns for the "Lazy H" can be found in just about any antenna handbook, but for those who do not have one handy, I have included a computer readout prepared by WA4HTR (now a Silent Key) and W4TDI, using the W7EL ELNEC program (Figures 4A and 4B).

Good luck to anyone who builds one of these antennas. I will be glad to answer any questions you may have, just include an SASE (RFD 1, Box 583, Colton NY 13625). And, if you have the space to build one for 40 or 80 meters, I would appreciate a report on the results. Fortune has never smiled on me—I have never had sufficient height to construct one of these.

\$49.95!

THE POWER STATION

The POWER STATION is a 12V x 6.5 AmpHr gel-cell battery complete with voltmeter, wall charger and a cord for charging via automobiles. It will power most

HT's at 5 Watts for 2-4 weeks (depending upon how long-winded you are). Also VHF, UHF, QRP, or HF mobiles such as the KENWOOD TS-50 (at 50W). There are no hidden costs, all you need is your mobile, HT power cord or cigarette lighter adapter.

The POWER STATION provides 12V from a cigarette plug and has two recessed terminals for hardwiring. A mini-phone jack with regulated 3V, 6V, or 9V output can be used separately for CD players, Walkmans, etc. THE POWER STATION can be charged in an automobile in only 3 hours, or in the home in 8 hours. The charger will automatically shut off when the battery is completely charged, so you can charge it even when it has only been slightly discharged, (unlike Ni-Cads that have memory). Our charging circuit uses voltage sensing circuitry, other brands are timed chargers which always charge the battery a full cycle, this damages their battery and shortens its' life if it only needs a partial charge. The POWER STATION has a voltmeter that shows the exact state of charge of the battery, not worthless idiot lights that tell you "YOUR BATTERY IS NOW DEAD." The voltmeter can even be used to measure voltages of other sources.

To order, send check or money order for \$49.95 + \$8.50 for shipping, along with your shipping address and telephone number to:

Add Remote-Base Capability to ANY Repeater!

Bargain bells 'n' whistles.

by Klaus Spies WB9YBM

Home-brewed and low-budget repeaters share a common problem: lack of bells 'n' whistles. Here's an easy project that will give you remote-base capability while keeping your repeater home-brewed, and/or low-budget.

Having worked some "rooftop DX" with my HT at the local repeater site, I felt working DX on 10m FM would be enhanced if it could be worked from such a good site. That led to the development of the schematic shown in Figure 1.

When the squelch signal of the repeater receiver goes positive, both the repeater

transmitter's PTT and the remote base transmitter's PTT are enabled through U1A and U2A. Then U3A, through two electronic switches (U4A & B), disables both the squelch signal and audio of the remote base receiver to avoid feedback.

When the squelch signal of the remote base receiver goes positive, the PTT of the remote base transmitter is disabled through U2A and U3B, while enabling the repeater's transmitter through U1A.

Since the FCC requires that you listen to a frequency before transmitting, separate on and off functions are available for

both the transmit and receiver sections of the remote base. These on/off functions can be tied directly into whatever DTMF decoder is currently available on the repeater.

Squelch signals should already be present in the repeater. For this circuit (depending on the type transceiver used as remote base), signal conditioning may be required (see Reference 1). This can be done with a single IC. If a margin of safety is desired in the transmitter, a very simple time-out timer can also be added (see Reference 2), as can a "hang" timer

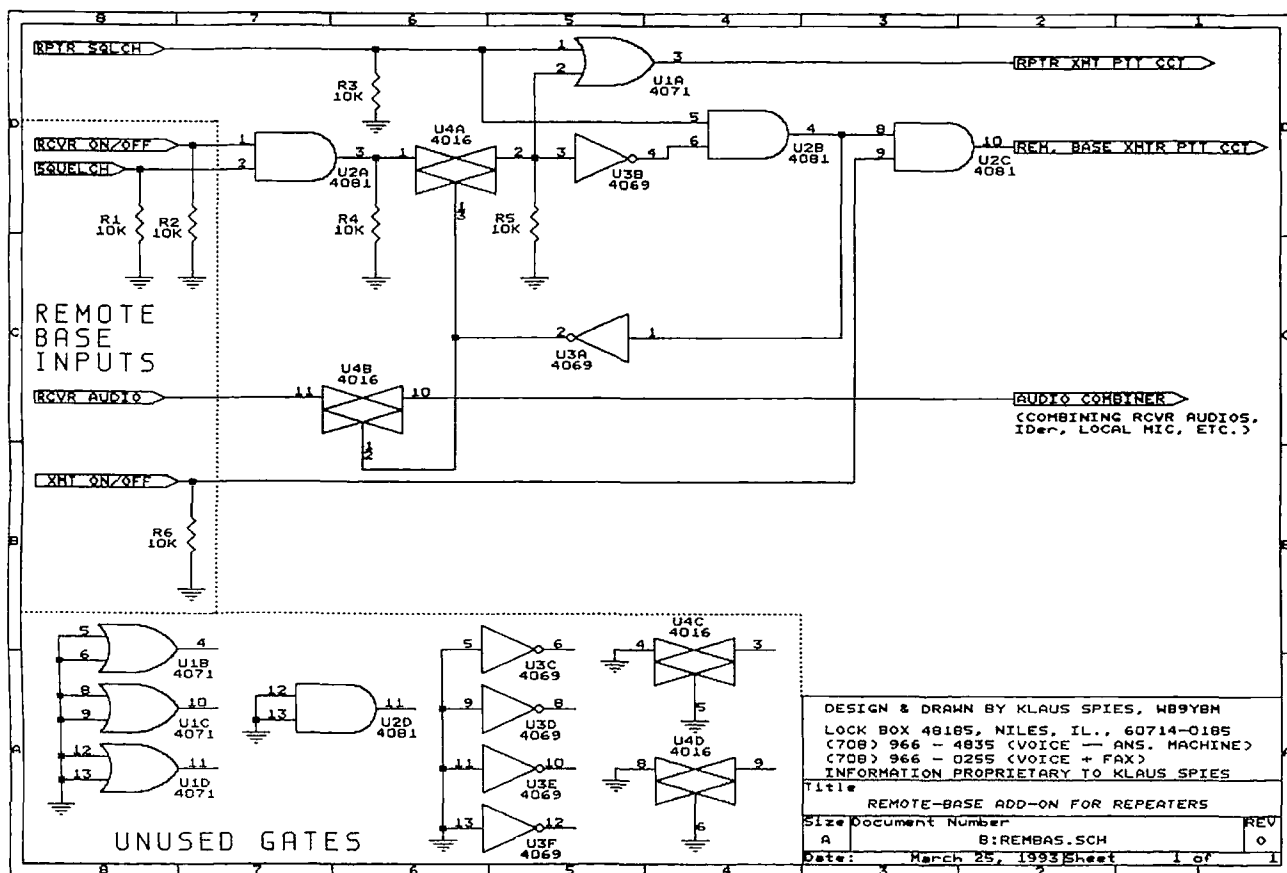

Figure 1. Schematic for remote-base add-on for repeaters.

Figure 2. PC board pattern and parts placement diagram.

(see Reference 3).

Since a repeater and a remote base deal with high RF energy, circuit construction should have appropriate safeguards: by-passing on all input/output leads, as a minimum. If installed in the repeater cabinet inside a shielded control section, no other shielding should be necessary. If this isn't the case, install the circuit in a metal box connected to power supply ground. **73**

DSP: The Whole Truth

*Everything you ever wanted to know about digital signal processing.**

**but were afraid to ask.*

by Ed Doubek N9RF

Designing Digital Processing into several police communication systems over the last few years produced some definite improvements in the quality of these systems. Applying the DSP principles to the reissuing of old recordings when they were released as compact discs has also helped to provide the quality the CD is noted for. This article will give you some insight into what the DSP systems can and cannot do, and will also suggest some low-cost modifications which can help to improve the quality of DSP-enhanced reception when used in amateur radio.

Digital Signal Processing seems to have taken the amateur radio community by storm. Many amateurs are not only asking how it works but how *well* it works. Manufacturers are rushing to provide this feature in new equipment so they can take advantage of this new-found miracle cure.

This article will give you a better insight into the working of a typical DSP system and will also provide a list of questions to ask yourself or a vendor when you are get-

ting ready to part with your hard-earned cash for a new station accessory.

Design of DSP Units

Figure 1 shows the hardware configuration of a typical Digital Signal Processing device. The hardware consists of an analog-to-digital converter that takes analog audio output of the receiver and converts it to a digital representation of the audio. The audio is processed in digital form and then converted back to an analog form with a digital-to-analog converter. It can then be amplified by a conventional audio amplifier and passed along to a speaker. After this processing, the final audio that is heard from the speaker can either be nearly identical to the original audio or it can be modified (corrected/improved) in the processing operation by removing unwanted distortion or noise from the audio signal. For narrow-band (communication) audio, a microprocessor operating at 30 to 40 MHz is typically used to enable several computations to be performed on each audio sample. The

typical sampling rate is at least two times the highest audio frequency to be processed. The NYQUIST rate is normally used since at this sampling rate the processor speed can be minimized and the distortion is minimal. The NYQUIST rate of sampling for a 3 kHz maximum transmitted audio frequency turns out to be 6 kHz.

In addition to the hardware, software is required to define the modification to be performed on the audio sample. The software is in fact the most variable part of the DSP system and causes the biggest variation in the DSP performance of the system. Normally one of two methods is used to program the processing. In the first case, an algorithm (formula) is used to process the signal and to generate the correction required to improve the audio. The second method is to look up the sampled audio in a table, then correct the audio based on what the table shows. In some cases, a combination of the two methods is used to correct the audio. Keep in mind that the more sophisticated the technique used, the more instructions per sample are required, and consequently the more expensive the software and the higher-speed hardware required to do the processing.

Features

Some DSP units are only suitable for eliminating heterodynes. Other units simply provide bandpass characteristics. The best systems employ an additional feature which provides a noise reduction mode as well as getting rid of white noise and pink noise. When purchasing a DSP unit, make sure the front panel gives you several modes of operation as well. If the mode switch provided is limited to just CW or SSB, it is probable the unit has either no noise reduction feature or one not adequately implemented.

Test Setup

Figure 2 shows the test arrangement that was used to determine what a DSP system can do to improve the quality of the audio and the intelligibility. This same test setup was also incorporated in a system to demonstrate the audio DSP technique to police departments. A cassette tape of good quality was mixed with a variable noise source to gradually reduce the intelligibility of the recording, then a comparison was made by switching in a JPS (NIR-10) DSP

Figure 1. The hardware configuration of a typical Digital Signal Processing device.

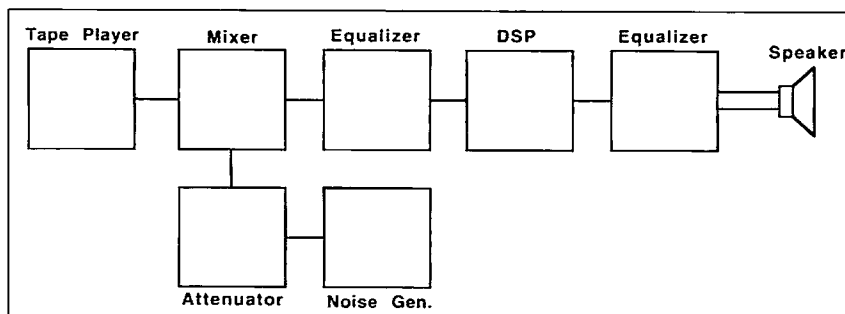

Figure 2. Test method.

Figure 3. Minimal analog implementation.

Figure 4. Note: Each equalizer is half of the stereo unit.

unit. When compared with the bandpass mode, the NIR (noise interference reduction) mode provides some rather dramatic results on voice signals. Improvements of between 6 to 10 dB have resulted, depending on the particular voice characteristic being processed. In most cases, a complete removal of all heterodynes is accomplished. The results in the noise reduction mode are not quite as good on CW because slow-speed CW looks like interference and gets completely removed. Above about 10 wpm CW can be processed with reasonable results. However, the bandpass filtering modes greatly improve the CW mode because of the nonexistent ringing. Normal CW filters in a receiver usually introduce ringing and other distortion when set to narrow passband.

DSP's most dramatic feature is its ability to completely eliminate (to the tune of 40 or more dB) any combination of constant or slowly-keyed heterodynes. In many units, a signal lasting for three ms or so in the NF mode is considered by the software to be a heterodyne and is removed. When in the NIR mode, a suddenly-appearing tone is removed after approximately 300 ms.

Can DSP Be Improved?

Yes, DSP can be improved. One of the problems that DSP exhibits is that as the amount of DSP action is increased, the amount of harmonic distortion of the lower frequencies being processed increases as well, resulting in a loss of intelligibility. When copying a heavily-accented voice signal, the DSP signal is even harder to understand. It has been shown that this distortion can be significantly removed by a change in the algorithm used by the processor, or by using an analog filter, as shown in Figure 3. Using a very sophisticated algorithm may require a faster microprocessor.

Another problem with DSP results from highly processed audio in the transmitter. Many non-DSP transmitter audio processors result in an increase in the harmonic distortion of the audio in the area of 1 kHz. This causes a loss of intelligibility at the receiver, especially when heavy DSP is applied to the received audio. In the case of heavily clipped FM audio resulting from some types of deviation control, the received audio may be almost impossible to understand when combined with an excited operator, a time of audio stress caused by an emergency, or when working a new country.

The Best Answer

In Figure 4, a dual-section seven-, 10- or

Figure 5. Equalizer curve.

15-band equalizer can be used to remove the audio response in the area of 800 to 1700 Hz. When one section of this filter is used to limit this band of frequencies ahead of the DSP unit and a second bandpass filter is used after the DSP unit, the improvement is dramatic and can almost double the effectiveness of the DSP system. When using this dual-band equalization, much of the distortion generated in the transmitter audio processor and received noise never enters the DSP unit and is never processed.

The second section of the equalizer is placed after the DSP unit and helps to improve the intelligibility of the processed audio. With this equalization, it has been shown that the audio can be intelligible with an increase of 3 to 6 dB of interference. A second benefit of this combination improves the intelligibility, even when using little DSP but while copying heavily compressed signals. For most receivers, cutting the spectrum below 300 Hz by at least 12 dB and the spectrum above 2.1 kHz by the same 12 dB removes all non-intelligence-bearing spectrum. The frequency range from 300 to 800 Hz should be boosted by 6 dB and the spectrum above 1700 Hz boosted by at least 9 dB.

Even though the audio processing improvements discovered by NASA use different response frequencies than those used in these experiments, the results are similar because of the overall receiver passband dissimilarities.

DSP in the Transmitter

Experimentation using DSP on transmitting has shown little improvement in experiments when the standard bandpass characteristic is used in the DSP units. When the

dual-band audio processing curve is used at both ends of the path, DSP does come into its own. An additional 3 to 6 dB of improvement results from this dual DSP implementation by packing the intelligence into two narrow bands rather than one wide band and further improves the intelligibility. This system is like using a 1.6 kHz filter in an SSB receiver without encountering the distortion the narrow filter generates.

DSP at IF Frequencies

If extremely high-speed microprocessors were available, DSP could be feasible in an amateur receiver IF. Because of availability and cost, this type of hardware would be impractical for amateur radio with today's state-of-the-art capabilities. Some pseudo DSP HF units have been implemented with prototype hardware, but they are not practical at this time. With DSP at IF frequencies, this filtering could theoretically place the receiver filtering much closer to the antenna, where it belongs.

Summary

Even without the DSP unit, the equalization curve shown in Figure 5 can be used after a receiver. These seven-band equalizer units are available for \$60 new, or can be obtained at many hamfests for \$15 to \$20. The more versatile 10- or 15-band equalizers make the implementation of this audio curve more accurate. Whether or not you are using DSP, the addition of audio correction to the audio output of your receiver can improve weak signal work, especially on 160 and 80 meters and VHF and UHF DX-ing.

Don't throw away your antenna just yet . . . DSP is good, but it has to have some signal to work on.

Recycled TV Beam to 2 Meters for \$2

Use an old TV antenna for this inexpensive, two-hour project.

by Marty Gammel KAØNAN

Last spring I was asked to supply a 2-meter beam for our local radio club's Field Day satellite contacts. Not having an extra beam, I found an old TV antenna someone had given me. There were many elements and the square boom was 92" long, perfect for the 11 dB gain needed.

Construction

First, I had to clean the boom of all elements and hardware. To do this, I used an electric drill to remove the rivets. Then I used a Scotch-Brite pad to clean any rust or

corrosion from the now empty boom and the removed aluminum elements.

I looked in a few antenna books for dimensions, settling on closely-spaced dimensions based on the NBS standard yagi design. There are many good books for finding workable spacing and element lengths. Using the *ARRL Antenna Handbook*, I developed the dimensions in Table 1 after reworking the spacing guidelines to come up with a seven-element beam that could be used in either vertical or horizontal polarization.

These measurements and spacing should give, in theory, over 11 dB gain, with a front-to-back ratio of 20-25 dB and good side rejection. Bandwidth for 1.5 SWR edges goes from 144.5 MHz to 147.750 MHz with 1.01 SWR at 146.250 to 146.5 MHz. If the beam is to be dedicated to SSB operation only, increase element lengths by 3/16" per MHz to shift the center frequency of operation down toward the bottom of the band.

There should be enough material to make all the elements from the material that you

strip off the boom. With all the material I had left, all I had to do was start measuring, marking and cutting. Take great care to drill all the holes squarely. The elements may be mounted either all *on* the boom or all *through* the boom. Mounting the elements through the boom will make a stronger, long-lasting beam, with less chance of elements working loose in the wind. I used stainless steel screws for mounting all of the elements.

Matching

You will need to make a matching network for this yagi. I chose a gamma match made from a piece of 3/8" aluminum tubing 7" long with a piece of RG-8 coax 7.75" long. I used the regular RG-8 coax; if you use RG-8 poly-foam coax you may need to change the length of coax for the gamma match.

To duplicate my gamma match, find a rubber or plastic cap that fits tightly over the end of the gamma tube (see Photo C). Strip the outer jacket and shield from the RG-8

Photo A. The raw materials.

Table 1.	
Reflector length 40"	
Driven element length 38.125"	
1st director length 36.875"	Spacing to driven element 15.75"
2nd director length 36.75"	Spacing to 1st director 11"
3rd director length 36.25"	Spacing to 2nd director 15.25"
4th director length 35.875"	Spacing to 3rd director 15.25"
5th director length 35.675"	Spacing to 4th director 15.25"
	Spacing to 5th director 15.25"

Photo B. Drilling out rivets to clean off the boom.

Figure 1. KAØNAN's 7-element 2 meter beam.

Figure 2. Gamma detail.

section of coax. Mount the center conductor and dielectric with a 1/2"-wide strip of aluminum or copper formed around the middle of the 3/8" tubing (see Photos C and D). Then mount an SO-239 panel mount connector to the boom with a piece of aluminum or copper perforated strapping. I was lucky enough to have some copper pipe hanger straps in my junk box to use for this.

Matching a gamma is fairly easy once you have the beam assembled. Mount the completed antenna on the mast about 7 to 8 feet above the ground. Set your radio to the center frequency that you designed for, place an SWR bridge between the radio and the antenna, then apply low power for your test transmission. Carefully note the SWR reading and slide the gamma in or out of the

Builder's Notes

A 1/4" drill bit should work well for drilling out the rivets holding the old elements to the boom. If you can get more than one old TV antenna to use as an element source, grab it—you can always use the extra materials for your next antenna project. When drilling the holes for elements, be sure that the elements fit snugly to help maintain squareness with the boom. You can cut the elements to length with a hacksaw, but file the rough-cut end smooth to ease the assembly of the beam. For the mounting screw holes I used a 1/16" drill bit; the screws should fit snugly.

Take your time when drilling and installing the elements to make sure that they are all centered and square to the boom.

Photo E. The completed beam.

Photo C. Gamma parts.

Photo D. View of the gamma.

gamma tube until you find the best match. Tighten the gamma to the driven element and you will be ready to install the antenna permanently.

Elements mounted out of alignment will distort the pattern and reduce the gain of the antenna.

Decide if you are going to mount the beam vertically or horizontally before drilling the element holes so that you can have the holes for clamping the boom to your mast in the proper plane. When the beam is to be vertical, you need to use a non-conducting mast to avoid detuning the beam and skewing the pattern.

I hope you enjoy using this beam and make many contacts with it. This project should take only a couple of hours from start to finish, once you have all the materials on hand.

Many thanks to John Berglund KØUBA for his help in editing this article.

Parts List

- Old TV antennas
- Electric drill or drill press
- 1/4" drill bit
- 1/16" drill bit
- Tape measure
- SO-239 panel mount fitting
- 1/2"-wide metal for gamma hanger
- Stainless steel screws (3/4" #4 self-tapping)
- RG-8 coax (short piece)
- Soldering iron
- Screwdriver
- Hacksaw
- Metal file
- Scotch-Brite pad
- 7" piece of 3/8" aluminum tubing
- Rubber or plastic cap for the gamma
- Marking pen or scribe (to mark measurements on metal)

A Discone Just For Fun

Fun to design, build and use.

by L. Scott Hall KAØDAQ

"What's wrong? Couldn't you make the last antenna work?" My wife always says this when I'm working on a new antenna. Putting up and taking down antennas is what I do in amateur radio. Anyway, that was a year ago last fall. It was a discone.

Does a discone sound high-tech? That's not how I made it, but it works.

First thing, when I decided on this project, I looked up what other people had to say about discones. Two references were found: *The ARRL Antenna Book* and *Home-Brew HF/VHF Handbook* by William Hood. I found Mr Hood's book to be particularly useful.

Defining the Project

A discone is a vertically polarized antenna with a disc (a capacitive hat 0.68 x the base width) on top and a cone a quarter wavelength at lowest frequency, from the vertex (the point at the top) to the edge of the base (an equilateral triangle from the side). The base is a quarter wave in diameter (see Figure 1). Mr Hood states that the disc should be spaced 6" from the cone vertex at 14 MHz (no formula was given). A discone should operate over a large frequency range. My plan was to use it on 10 and 15 meters. I took these numbers and plugged them into my pocket computer to run them a few times.

```
10: Input F
20: B=492/(2*F) or B=150/(2*F)
    for metric
30: D=0.68*B
40: Print B,D
50: Go to 10
```

Nothing fancy here—just the bare bones. Where F equals the lowest usable frequency. B equals base diameter and D equals the disc diameter.

The final design used 20.5 MHz as the lowest frequency because the SWR is supposed to rise rapidly at the lowest usable frequency. 20.5 MHz is a little below the 15 meter band, but I wanted the SWR to be low all the way to the bottom of the band. And it made the math easy. My final dimensions were 8'2" for the disc, 12' for the cone, and 4" for the spacing (I guessed for the spacing).

Before beginning I had to determine the number of radials to use. My reference book said one radial every 1/50 of a wave. That

would be 38 or 40 radials. I didn't believe this number, so I did some experimenting.

Modeling

I decided to build a model. The commercial FM band (88-108 MHz) often uses dual polarization. A discone should work on the vertical portion. A tin can about 4" in diameter was used for the vertex, with a hole in the remaining end for the coax, and 12 small holes punched around the open end to attach the cone radials. The coax is fed through the open end, then through the coax hole, with the braid pulled back 2" and soldered to the can. The 2" of insulated center conductor is fed through a 1" thick, 8" wide wooden disk. Two short screws hold the can to the disk. Any insulation on the coax above the wood

cut in the radials ends and crimped for a good mechanical connection.

After the top hat was up, I strung only two cone radials (stranded wire) from the can to start with (a stiff wire base loop was used to hold the radials in place). A small-diameter stick held to the vertex can by one screw was all the support needed. Hooking this up to an FM receiver with a signal strength meter, I was surprised to find it bidirectional. Adding a third was better. After six radials, gain was not noticeable on my equipment. I guess 1/50th of a wave for radial spacing meant without a base wire.

Since I planned on using a base wire to tie all the radials together, I decided on 15 radials per wave, or 12 for this antenna. I chose 12 radials for a better SWR on 10 and for lots of capture area.

Mounting Problems

The cone and disc for the full-size discone are very much like the test model's: a circle of plywood holding six elements, with the far ends shorted together to form the disc and 12 stranded copper wires hanging from a tin can and attached at the bottom to the base loop. The real problem is the supporting hardware. Holding up a tiny model is a lot easier than a disc over 8' across. The parts for this antenna sat around a long time before I finally came up with something I thought would work.

I always knew I'd use a 1-1/2" steel mast for supporting the antenna, but how could I attach it without any possibility of shorting out the cone and disc, yet still holding the disc 4" above the cone?

Mounting Solutions

The mount (spacers) consists of three pieces of 2x4 and a 5" circle of plywood (the 2x4s are 15", 8" and 3-1/2" long). First the 15" and 8" 2x4's were glued together (I used a hot glue gun) with their centers aligned (see Figure 3). A 1/2" hole drilled down the center gave me room to feed the coax through.

I heated up the glue gun again and stuck these two, the large end, to the bottom of the disc. I made sure that the hole in the disc and the spacers were lined up right. The can already had 12 holes punched in it for the radials and the coax hole in the remaining end. After slipping the coax through the hole I stripped off 5" of insulation, then bent

Photo A. The discone.

is stripped off. I poked a hole in the center of the tin can lid (the one removed to empty the can) and soldered it to the center conductor on top of the disk. The disc radials (six broken TV antenna elements cut to 11") were attached with screws, and the outside ends joined with a copper wire through a slit

Figure 1. Discone measurements.

back and soldered the shield to the top of the can.

This is when I should have soldered the radials on to the can, but no, I did it the hard way. I slipped the center conductor through the center hole and, using more hot glue, pressed the can into place. I drilled a coax hole in the center of the 5" plywood circle and a mast hole in the 2x4 before gluing them together (see Figure 3). The plywood fit snugly into the can. And the mast, with the coax slipped through it, fit snugly into the 2x4 mast hole. This 2x4 collar keeps the mast from shifting. The plywood circle supports the weight of the whole antenna on the top of the mast.

Remember how on Field Day everyone puts up lightweight masts with guy lines? Now turn that picture upside down; that's how I hold the disc level. A guy line ring is mounted 3' down from the disc and four evenly-spaced ropes are tied from the edge of the 2' plywood disc to the guy ring (see Figure 2). This does a great job of holding

the disc steady.

A stiff wire simply wasn't going to hold 12 radials in place as on the model. I used a stranded wire for the base loop and six 6' sticks (1" x 1"). Two parallel holes were drilled in each stick, one through each end. While soldering the radials to the base loop, I slipped a stick on after every two radials. When all the radials and sticks were in place and the base wire was soldered together, I brought all six ends together around the mast and threaded a rope through the end holes. Then, taking up the slack, I pulled them all tight to the mast, like the spokes of a wheel, and tied them off level with the base loop.

Wrap Up

When I turned on the receiver the first

time I knew I had a winner, it worked great. Signals were coming in from everywhere. This antenna worked just like the books said it would: low SWR over a broad bandwidth, and a low angle of radiation for DX. At least this is true for the lowest 10 MHz I played with. Theory states the this discone should have a working bandwidth from 20.5 MHz to 205 MHz, but without VHF equipment I was unable to prove it.

My discone was fun to design, build and use. It had good receive and transmit qualities. I liked it, but it had some problems. Foremost, it pulls in signals from everywhere, not a good quality on crowded bands or in contests. With these qualities it might work well for a net control station, but not a good choice for your only antenna.

My first antenna was a 40 meter dipole, stretched between two pine trees in the back yard. The center insulator was a piece of Plexiglas. The unsupported coax hung down from the center of the antenna and draped across the telephone wires, eventually making it into my bedroom window. Not having much in the way of adult electronic supervision, I had simply stripped the coax back and soldered it to the wires at either side of the insulator. This worked pretty well, and gave me a low VSWR as well as a feeling of great pride. I began racking up contacts that were several states away! However, it wasn't long before my range started to decrease. I tested the antenna, and the VSWR was still quite low. I didn't have a real power meter, but the meter readings on my trusty ol' Drake 2NT were the same as always. It even lit up my dummy load (100 watt GE Soft-White) as bright as always, but my buddy could barely hear me across town. What was up?

It took a visit from an Elmer to point out the obvious problem. In my haste to erect the antenna I had simply soldered the coax to the wires at the insulator. I hadn't even looped the coax over the insulator for strain relief. Rain was collecting on the dipole elements, running downhill to the insulator, and filling my unprotected coax up to the brim. It only took a few showers before my cheap TV-store coax had a saturated dielectric, and was acting more like a dummy load than a transmission line. I had plenty of power going into the line at the transmitter, but none of it was making it out to the antenna. My 75 watts of crystal-controlled CW signal was simply heating up the coax. In retrospect, it seems that anyone with half a brain would never have had this problem in the first place. However, it did teach me that things electronic are seldom exactly what they seem, even if the tools you have tell you that everything is in order.

The Solution: A Field Strength Meter

There was only one tool that would have given me an indication of my problem, and that was something that would have measured the strength of the actual field being radiated from the dipole. Strangely

enough, the device is called a Field Strength Meter. (In actuality, the other method would have been to measure the power at the junction of the coax and the antenna. This method has been suggested in various texts, but I had a problem with it. For one thing, I didn't have a power meter. More importantly, I never figured out how to get up to the junction of the dipole when it's strung between

two trees with the feedline dangling straight down. My family didn't own a bucket truck. (This is another one of those things they just didn't explain in the *Handbook*.) In any event, had I taken a couple of reference readings with a field strength meter and jotted them into my log book, I would have had a pretty good idea of where the problem was. At least I would have understood that there was a real problem, and that I wasn't just losing my marbles.

A new entry in the field strength meter field is the DIGI-FIELD unit, produced by IC Engineering of Encino, California. The DIGI-FIELD is a self-contained battery-operated field strength meter in a 3" x 4.2" x 1.5" heavy-duty plastic box. The unit comes with a 3-1/2 digit LCD display, an SO-239 connector, and an output jack for monitoring the demodulated (AM) signal. The range of the meter is from DC to 12 GHz, which should cover most of your ham applications. (By the way, IC Engineering is happy to supply spec sheets and charts on request.)

The basic design of any field strength meter is fairly simple. An antenna feeds an RF signal to a diode rectifier. The rectified voltage is then filtered by a capacitor, and the resulting DC voltage is measured by a meter. This system has worked fairly well for years. The only problem with it is that it takes a fair amount of energy to produce enough force to deflect even the most sensitive meter movement. In other words, the standard field strength meter tends to be somewhat "deaf." Several schemes are available to increase the sensitivity of the units—some use tuned RF filter circuits that resonate at the desired frequency, some use broadband amplifiers, some use a simple transistor amplifier that follows the detector diode.

The DIGI-FIELD meter approaches the problem from another angle. It does away with the mechanical meter movement, replacing it with a solid-state LCD display. The input impedance of the digital meter is much higher than any mechanical meter, so less voltage is required to produce a usable reading at a given frequency. The result is a higher sensitivity meter with no front-end to tune. As an example, a standard tuned-RF

The DIGI-FIELD Field Strength Meter.

single-transistor field strength meter was compared to the DIGI-FIELD. Feeding a signal into the standard meter with a signal generator produced a "usable" needle deflection with an input signal of 500 mV at 146.000 MHz. The DIGI-FIELD meter produced a "usable" reading with only 80 mV. (Since the field strength meters compared had mechanical and digital meters that both read in relative, not absolute, units, this type of test may seem like "comparing apples to oranges." However, the minimum "usable" reading was that deemed to be useful during an antenna peaking operation, similar to tuning up a transmitter or perhaps foxhunting. This was actually about one-quarter scale on the mechanical meter, and about 1.0 units on the digital display.) This means the DIGI-FIELD is able to pick up weaker, more distant, or lower power signals.

So who needs a field strength meter? Well, if you've just picked up your first ham license you'll probably want to invest in one or two other instruments first—a good DVM, maybe a VSWR bridge. Then, if you find yourself drawn to antennas and antenna design, a good field strength meter is a necessity. The DIGI-FIELD can be used to plot the gain of various yagi antennas you might be building, or to compare one antenna to another. You can compare the effectiveness of various styles of antennas on your HT. Reference values can be taken on your HF antenna to make sure its performance is up to par. Around the shack, a field strength meter can let you sniff out bad coax connections or improperly grounded transmitters. As an educational tool, the DIGI-FIELD can be used to demonstrate the concept of gain, or antenna polarization.

Using the DIGI-FIELD

Operation of the DIGI-FIELD is quite straightforward—you turn it on and plug an antenna into the SO-239. RF measurements will appear on the display. Like most field strength meters, the readings are relative, and are normally used in a comparative manner. For example, to adjust the spacing on a yagi for maximum forward gain you might set up the antenna and meter a reasonable distance apart, and key the transmitter. Note the reading on the DIGI-FIELD, and make an adjustment to the antenna. Take another reading, adjust accordingly, and so on. The sensitivity of the meter can be adjusted by moving the telescoping antenna up and down, or by connecting a conventional antenna to the input jack. The DIGI-FIELD does lack a bar graph display, which would be handy in operations that are looking only for a peak, such as foxhunting. However, the LCD display does respond quickly enough to allow these types of jobs to be performed—just not as easily.

All in all, due to its high sensitivity and wide bandwidth, the IC Engineering DIGI-FIELD represents a reasonable investment, and antenna buffs will find it to be extremely useful.

The Boyd Electronics RF Sweep Generator

Building and experimenting with RF circuits can be performed with a simple continuous wave (CW) signal generator, but the avid technician quickly learns that an RF sweep generator is a real asset on the bench. A sweep generator repetitively tunes through its set range of frequencies, thereby allowing you to examine the frequency response of the circuit under test on an oscilloscope. Circuits that test better on a sweep generator compared to a CW signal generator include:

- High-pass and low-pass filters
- Bandpass filters
- L-C tuning circuits
- Antenna tuners
- Crystal, ceramic or mechanical IF filters
- RF amplifiers
- Video amplifiers
- IF amplifiers

Sweep generators are used by service technicians to test and align radio

and TV equipment, and they are also used by engineers and technicians in laboratory settings. The service grade sweep signal generators may be cheaper than laboratory models, but they usually don't cover all frequencies that amateurs need. The lab models are in the multi-kilobuck price range, so they are out of the game as far as most hams are concerned. Perhaps the best alternative is to build your own sweep generator from a kit.

Last month, an advertisement by Boyd Electronics (1998 Southgate Way, Grants Pass OR; 503-476-9583) in 73 caught my eye. They offer the Model RSG-30 RF sweep generator as a kit at a very attractive price. So, I contacted Jerry Boyd, and he shipped an RSG-30 kit for review. (He also offers two assembled versions, but considering most hams would probably build the kit, I wanted to assemble this one myself. Besides, building stuff is one of the fun parts of doing this column.)

RSG-30 Features

The Boyd RSG-30 offers sweep from 2 to 30 MHz, and has the stan-

dard 50 ohm load needed for RF circuit testing. The output level is approximately 100 mV RMS, and sweep width is variable from 5 kHz to 30 MHz. A negative 12 volt, 20 ms trigger pulse is provided so the oscilloscope can be triggered in step with the sweep (which makes the presentation coherent).

Three modes are offered in the Boyd RSG-30: CW, Video and Symmetrical. The CW mode outputs a continuous, non-swept signal (Photo A) on

"The lab models are in the multi-kilobuck price range, so they are out of the game as far as most hams are concerned. Perhaps the best alternative is to build your own sweep generator from a kit."

a single frequency set by the front panel FREQUENCY control. It can be used in the same manner as any RF signal generator. The VIDEO mode is a swept

mode in which the RF frequency is swept from 2 to 30 MHz, while the SYMMETRICAL mode is a swept mode in which the width of the sweep (min to max frequency) is set by a SWEEP WIDTH control on the front panel (5 kHz to 30 MHz). Photo B shows the waveform on my oscilloscope when the SYMMETRICAL mode was selected and the SWEEP WIDTH was set close to maximum (so it is similar to the VIDEO mode).

RSG-30 Internal Circuitry

Figure 1 shows the block diagram of the Boyd RSG-30 circuitry. The RF signal is formed by mixing together two other signals: the output of a 50 MHz crystal oscillator, and a 52 to 80 MHz voltage tuned oscillator (VCO). A VCO is a circuit in which the RF frequency is set by a tuning voltage applied to a voltage variable capacitance diode (or "varicap"). The output of the mixer is the 2 to 30 MHz difference between the crystal oscillator (XO) and VCO signals, and this signal is filtered in a low-pass filter to remove the remaining components of the XO and VCO. The 2 to 30 MHz filtered signal is amplified by a Mini-Circuits MAR-1 MMIC amplifier. These amplifier ICs have a natural 50 ohm output.

The sweep and tuning voltage section contains a clock-driven sawtoothed generator, as well as DC offset circuitry for setting the center frequen-

Photo A. Sine wave CW output of the RSG-30.

Photo B. Swept RF output of the RSG-30.

Photo C. Output of the circuit under test on oscilloscope screen.

Photo D. Output of detector on oscilloscope screen.

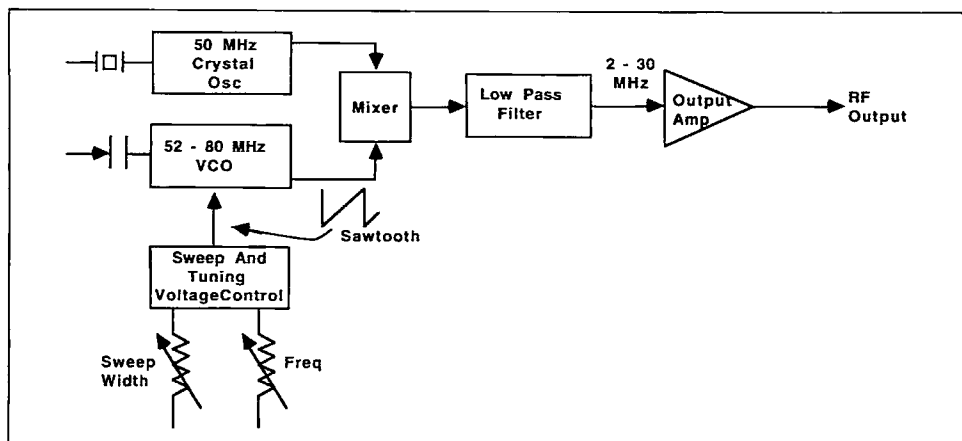

Figure 1. Block diagram of the RSG-30.

cy. The saw-toothed waveform allows the VCO to sweep linearly from a low to high frequency, and then snap back to the low frequency end of the swept spectrum. Both the sweep width and center frequency controls are part of the sweep circuit.

Using the RSG-30 RF Sweep Signal Generator

There are two basic ways to use the Boyd RSG-30 sweep signal generator. If you have an oscilloscope that has a 30 MHz (or greater) bandwidth, or if you can be satisfied limiting the RSG-30 to a lower bandwidth (say, 10 MHz), then the RSG-30 can be hooked up as in Figure 2. The SYNC connector on

the rear panel of the RSG-30 is connected to the EXTERNAL TRIGGER input on the oscilloscope. The RF output of the RSG-30 is fed to the input of the circuit under test (CUT). The output of the CUT is fed to the high frequency vertical input of the oscilloscope.

Photo C shows the waveform to expect when the RF is viewed directly. This particular trace was taken when the CUT was a 10.7 MHz IF transformer (the type used in FM broadcast receivers). A narrower filter would produce a similar trace, but with less width. In some cases, users prefer to lower the trace to the oscilloscope baseline so that only the top portion of the symmetrical waveform shows.

Many amateurs have oscilloscopes these days, but many of them are low frequency oscilloscopes found at ham-fests, government surplus, industry, or electronic repair shops. These oscilloscopes are not suitable for direct use with the RSG-30. If the hook-up of Figure 2 is broken at "X," however, we can insert a detector circuit. Some people use a demodulator probe for the oscilloscope, while others use the circuit of Figure 3. This circuit should be built inside a small shielded metal box. It consists of a diode detector (D1) and a filter capacitor (C2). The other capacitor is used for DC blocking to prevent any DC from the CUT from messing up the diode.

The diode used in Figure 3 is a germanium detector diode such as 1N34 or 1N60. These diodes are usually available at Radio Shack or at electronics parts places that sell Jim-Paks. Another source of the diodes is the service shop replacement lines of semiconductor such as NTE or ECG products. In those lines, the ECG-109 and NTE-109 are suitable.

Photo D shows the waveform to expect when using the diode detector. This waveform was taken from a 40 meter RF tuned circuit consisting of a disk ceramic capacitor and a 4.9 μ H toroidal inductor. The diode detector and filter removes the residual RF, and presents just the instantaneous DC output of the detector.

Boyd Electronics offers the RSG-30 in several ways. First, you can buy a kit consisting of the printed circuit board and all parts needed for the PCB board (RSG-30K). This costs \$59.95. They will also assemble and test this version for \$119 (order RSG-30A). For these options you will have to supply certain mechanical parts and the cabinet. Boyd Electronics gives you the Radio Shack part numbers. The company supplies a pair of adhesive templates that stick to the front and rear panels, and give the unit a real professional look. If you want the RSG-30 with a cabinet, then order RSG-30C for \$159.

Next month, we will take a look at some sweep generator applications, including a low frequency adapter for the RSG-30 that permits it to be used below 2 MHz.

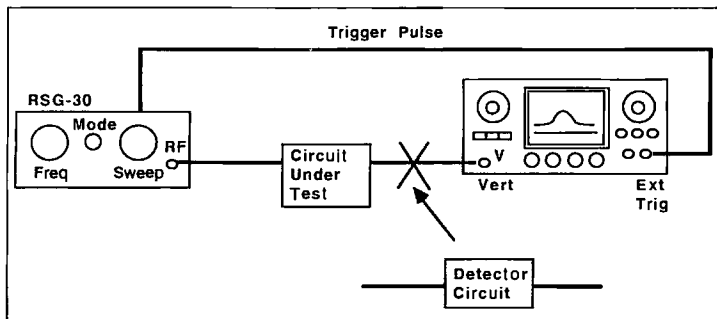

Figure 2. Normal set-up for the RSG-30 to test an RF circuit.

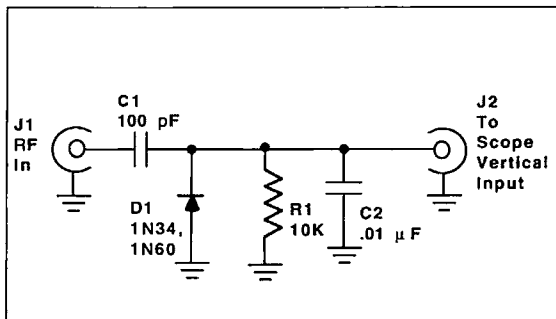

Figure 3. Simple detector circuit.

Amateur Radio Via Satellites

Andy MacAllister WA5ZIB
14714 Knights Way Drive
Houston TX 77083

At this time last year, AMSAT-OSCAR-13 was in perfect operating condition. The satellite was more than four years old and performing flawlessly. In recent months though, the situation has changed.

In May, the transmitter section of the "JL" mode transponder (23 cm or 2 meters up with 70 cm down) stopped working. All attempts to bring the 70 cm transmitter back on line failed. Studies of the satellite telemetry indicated that the exciter portion of the transmitter was functional but the power-amplifier section was not. This turn of events has placed greater emphasis on the popular mode "B" (70 cm up and 2 meters down) and more exotic mode "S" operation (70 cm up and 13 cm down).

Satellite controller James Miller G3RUH has reported that the 23 cm receiver still functions well and is being used for satellite control activity. G3RUH, DB2OS and VK5AGR have revised the 1993 and 1994 operating schedule without mode "JL" for A-O-13. It appears in Table 1. No further anomalies have been reported.

Field Day 1993

The loss of two modes via A-O-13 did not dampen satellite activity during Field Day in June. Passes over North America for both high and low orbit satellites were almost continuous for the 24-hour event. Many times, more than one active ham sat was above the horizon and available for contacts.

A-O-13 was excellent, especially during the morning hours of Sunday June 27th. Modest directional antennas provided many portable stations "armchair copy" when the satellite pointing angle favored their locations. While most stations focused on mode "B" operation, a few tried "S" reception on 2400 MHz with loop yagis, helix arrays and small dish antennas. The two-foot dish used at K5DX by our group did not work, but later investigation of the downconverter circuitry revealed some minor wiring errors. The two-footer (an old snow coaster) with a Down East Microwave converter (RR 1 Box 2310, Troy ME 04987; Tel: 207-948-3741, Fax: 207-948-5157, catalog available) can hear the satellite when properly connected and aligned. Steve KE5O heard several stations working mode "S" on Field Day, and worked one. His system included a surplus six-foot dish and a

patchwork downconverter with a 7 dB noise figure and no preamp.

Many other satellites were available for Field Day. Full-OSCAR-20 had been commanded to the analog mode (voice and CW) for the event. RS-10 was working well with mode "A" (2 meters up and 10 meters down). RS-12 was on, but the 15 meter uplink was overrun with terrestrial activity; the earth-bound operators were obviously unaware of their interference with satellite operators. AMSAT-OSCAR-21 was in the FM repeater mode using 70 cm up and 2 meters down.

The microsats were operational with 1200 bps PSK (phase-shift keying) on LUSAT-OSCAR-19 and AMSAT-OSCAR-16, and 9600 bps on UoSAT-OSCAR-22 and KITSAT-OSCAR-23. ARRL Field Day rules do not recognize contacts with the digital satellites, but the concurrent AMSAT Field Day rules encouraged uploading Field Day greeting messages and

downloading messages sent to the flying BBSs by other groups working the event.

Mir was in the sky and a few lucky folks managed contacts with the Shuttle Amateur Radio Experiment (SAREX) on STS-57. N5WQW operated some voice, and on some passes the W5RRR-1 robot was available for packet connects.

AMSAT Space Symposium

The eleventh annual AMSAT Space Symposium will be held from October 7-10, 1993, at the La Quinta Inn in Arlington, Texas. It will be hosted by the North Texas AMSAT Group and promises to be a great weekend.

Beginning on Thursday morning, October 7, at 9 a.m., those attending are invited to meet at the La Quinta Inn (State Highway 360 and Interstate 30) for a tour of various electronic surplus stores in the Dallas/Fort Worth

Photo A. Field Day 1993 at K5DX in central Texas. WA5ZIB repairing the 9600 bps TNC for U-O-22 and K-O-23 contacts.

Table 1. Provisional event schedule for A-O-13 through 1993 and 1994.

area. Transportation and a guide will be provided.

Official registration begins Friday morning at the Inn. An antenna test range will be set up near the hotel for those wishing to test their favorite satellite antennas. The first of many line technical papers will be presented Friday afternoon in the La Quinta Conference Center. Friday evening is open for dinner with friends and family or a visit to the stadium next door for a Texas Rangers baseball game.

Saturday begins early with a full day of presentations and demonstrations. This is a great opportunity to find out what's new in the amateur satellite field. Topics include the Phase 3D satellite project, Pacsats, DSP modems, microwave communications and much more.

Saturday evening starts out with the traditional "altitude adjustment" hour followed by a banquet dinner with keynote speaker. Presentations and prize drawings follow 'til almost midnight. While dress is casual for the symposium, jeans are not suggested for the banquet.

For those who can stay, Sunday activities include a beginners' forum and other technical sessions. There is also the AMSAT Board of Directors' meeting in the afternoon.

Access to the area is easy. For those flying in to DFW airport, there is a free hotel shuttle to the La Quinta

Inn. Call the La Quinta at 1-800-531-5900 to reserve your room before September 24th to get special rates of \$50 for a single, \$55 for a double or \$60 for a triple/quad. Suites are also available.

To preregister for the AMSAT Symposium, send \$15 for registration only, or \$35 for registration and the Saturday night banquet to: 1993 AMSAT Symposium, Route 1 Box 291, Waco TX 76712. Preregistration

is encouraged for those wishing to attend the banquet. This will be the third time the AMSAT Symposium has come to Texas and it promises to be one of the best. I'll see you in Arlington. **73**

THE ANSWER IS GAP TECHNOLOGY • THE ANSWER IS GAP TECHNOLOGY • THE ANSWER IS GAP TECHNOLOGY

Q A backyard antenna for the low bands at a low cost? A Yes...the answer is GAP'S revolutionary Voyager.

If you're looking for an antenna that can outperform the others and give you the edge, you're looking for a GAP. The GAP Voyager DX-IV is not another "add a kit" antenna for 160 meters. It is the first antenna manufactured specifically to provide efficient low band operation from the typical backyard without a huge investment in time, money and

space. The Voyager is the first and only antenna to cover the entire 75/80m under 2 to 1. Put it up. Turn it on. No tuning. No frustration. GAP delivers everything but the hassles. And — GAP delivers at a fraction of the cost of the "so-called" competition.

Comments from the Survey

Yes, it took a long time, but I am finally getting a chance to compile the information from your survey responses. I am going to do this in two parts: This month I'll look at some of the comments and respond to them; next month (along with a special treat for those of you interested in TCP/IP), I'll give you the tabulated "statistics."

First, I really want to thank those who took the time to respond; your comments were thoughtful and helpful. I also want to thank those of you who made kind remarks about the column—a lot of what you said (perhaps without you even knowing it) gave me the impression that this column is a success. Though I can't please everyone, I want to provide you with information that is *useful* and *understandable*. You tell me I have been doing that. I even got a few suggestions on what I am doing wrong; I need those too. Please do not hesitate to let me know what you think. Just because the official survey may have ended doesn't mean that I want your input to end too! Write to me at the address at the top of the column or, much better, at my electronic mail address on the Internet: jsloman@bix.com. I really enjoy hearing from you on packet, too, but PLEASE—no business! I have had to ignore a couple of requests for things like reprint permission that have come that way. To contact me via packet use: N1EWO@N0ARY.#NO-CAL.CA.USA.NOAM.

OK, on to the comments. Many of you had very similar things to say, so I tried to pick representative examples. I wish I had the time and space to discuss every response—really, Bill N6XIV asks for "... more entry level plain talk ..." and is joined by Joel N2GOA who says, "KISS, for me, anyway." I am pretty sure that Joel is asking me to "Keep it Simple, Stupid" and not something that my wife needs to be jealous about. Other comments in this vein come from Bill N8NJA who asks that all ham radio writers keep this idea in mind, and Roger WD8DJR who laments the poor quality of some TNC manuals and asks manufacturers to "walk a new user through a complete setup." To those of you with these feelings, I will endeavor to provide you with the basic information you seek. I understand your frustration with the incorrect assumption made by many technical manual writers that everyone knows a lot more than they do. I struggle with this in all of my techni-

cal writing—being reminded doesn't hurt.

On the other end of the scale, Don KI5SS asks for articles on "advanced topics," listing data lists, block diagrams of multimode stations for satellite ops, and equipment lists for setting up those stations. I think you will find what you want, Don, in future issues. Steve N8AMW will also get what he asks for—technical info on PACTOR, an exciting new mode which is catching on like wildfire.

A lot of you, including Mitchell KC6SXY, asked for practically-oriented columns—something I like to do anyway. You'll be seeing lots of those. Mitchell also went on to give some good advice which he asked me to pass on: "Tell people they should *never* install a board into their computer without also carefully recording and attaching to the machine what they have installed and the settings. They should also immediately place the manuals in a cherished, preserved three-ring binder. Without these steps you may end up with a computer that is a total mystery to you." (I hope Mitchell doesn't mind the copy editing—my editors do it to me all the time.)

I agree with Mitchell on this one, and I have never discussed it here so thanks for bringing it up. The IBM-PC allows us the flexibility of inserting multiple adapter cards but, unfortunately, it has no way of automatically keeping track. Today there is a proliferation of communications and I/O (Input/Output) devices. The average computer user can insert these in his or her machine: scanners, fax boards, internal modems, internal TNCs, network cards, voice mail boards, and even more. The biggest problem is that all of these cards are competing for certain limited resources.

The IBM-PC has four types of resources that hardware adapters might want or need:

- IRQ (Interrupt ReQuest line or level)
- I/O port addresses
- Mapped memory addresses
- DMA channels (Direct Memory Access)

IRQ

The IBM-PC uses an *interrupt driven* architecture. What does that mean? It means that the designers of the PC decided to implement a system of hardware services that relies upon a request from the hardware device. How you service your hardware's needs is a basic problem of computer design. To make this a little clearer, let's take a look at a familiar example—the com port.

The PC com port is an asyn-

chronous device; that is, the data can appear at any time. Its flip side is the synchronous communications port, which is controlled by a standard clock on one end of the connection. With the PC's async port, timing is controlled by start and stop bits sent with the data. If you don't completely understand, don't worry—here's the bottom line: Since the Central Processing Unit or CPU (the computer equivalent to a brain) can't tell when the data is going to appear at the com port, it can do one of two things. It can keep checking the port over and over to see if anything is there, a process called *polling*. Or, as the PC does, it can wait for an interrupt request—sent by the com port when it gets data—and then service it. You can see now why it is called an "interrupt": It literally interrupts the CPU and asks for service.

On the PC the interrupts have various priority levels with "0" having the highest and higher numbers getting lower in priority. IRQ0, for example, is the timer interrupt—think of it as the computer's heartbeat. The AT version of the PC has 16 interrupts, though not all of these are available for your use. Some interrupts are reserved for the system.

As you can see from Table 1, IRQs 11, 12, 14, and 15 are "officially" available. The trouble is, you need a 16-bit card to use these! Why? An IRQ is a physical hardware connection to the bus. A 16-bit connector is needed to make those physical connections to the higher IRQs. Though it is changing, many cards still cannot use the higher interrupts.

What can you do? Fortunately, some of the "reserved" IRQ slots are rarely used by the hardware that is supposed to use them. For example, you can probably go ahead and use IRQs 5 and 7 without any ill effects. If you do not have a com port set for COM1 or COM2, you can use the associated interrupt. You can even "share" interrupts in some cases. This is risky business, though. First you have to find two boards that can get along with each other. This usually works best in the case of something like a scanner (image, not police!) that doesn't "wake up" until its special software is loaded. You can share the IRQ with another piece of equipment that is also well behaved AND WON'T BE NEEDED AT THE SAME TIME. In any other case, each adapter needs its own IRQ. So back to our original advice of writing stuff down: You need to know which IRQs are available when it is time to configure that new board.

I/O Port Addresses

Another resource, less scarce than the IRQs, is I/O port space. This is a memory space, distinct from RAM (Random Access Memory)—the place programs live while running—which is used to let hardware transfer data to programs. I/O ports are usually specified in terms of a

"base address"; this indicates where the I/O port begins in memory. Many adapters use I/O ports—sound cards, scanners, NICs (Network Interface Cards), and fancy display adapters are a few examples. Conflicts among cards for I/O space is not too common—but it does happen. Sound cards and scanner boards are often culprits. Most are flexible enough in where they can live that you will be able to find a spot that doesn't conflict. On the other hand, keep in mind that you may have two pieces of hardware that just don't get along!

Mapped Memory Addresses

Though it used to be uncommon, using mapped memory seems to be becoming more popular. This technique takes up a number of memory addresses in the 640K to 1024K range—(known as the Upper Memory Area or UMA) and *maps* the data to some memory that is physically resident on an adapter. This is much faster than I/O port techniques, and so you will find it on display adapters, NICs, and other applications which have to move a lot of data. The UMA space was set aside by PC designers for this purpose but was recently taken back to "load high" programs and the like. This is where a conflict might occur. In the context of our current discussion, write this stuff down with the rest of your information so you can tell if you've got a conflict between two adapters.

DMA Channels

The last of these resources are the DMA channels. DMA means Direct Memory Access, which is a technique to allow adapters to quickly access information stored in your RAM—without the assistance of the CPU. This is very important to some operations performed by scanners and other devices which have to move a lot of data in a hurry. On the AT there are seven DMA channels, but not all are available. This is usually not a source of conflict, but, if you have a sound board, you may do some juggling before you can install a second DMA-using board.

What Should You Write Down?

Make yourself a little chart with a line for each slot in your computer (you can't install more boards than slots!). Across your chart put the following headings:

- Manufacturer
- Model
- Serial Number
- Function
- IRQ
- I/O Port
- DMA Channel(s)
- Mapped Memory

Manufacturer is obvious: Who made the thing? Model and serial number are very important. When it comes time to get tech support help, this may just save you the time and frustration of opening your machine

Number 17 on your Feedback card

Amateur Radio Teletype

Marc I. Leavey, M.D., W3AJR
6 Jenny Lane
Baltimore MD 21208

I thought I might take this month when the kids are going back to school to play professor, myself, and answer some of your questions.

We'll lead off this month with an Email message that arrived via America Online. Matthew Mucker KB5FWG says that he has two very beginner-level questions for me. As a college student on a budget, he has never exercised the privileges ham radio offers. He's been monitoring 144-148 MHz in Houston, though, and wants to get in on the action, but his budget, and good ol' ham radio spirit, has prompted him to try to build his own 2 meter radio. Looking through two or three current magazines, he has not found any which give detailed information. He is looking for references he could use to accomplish this task.

Second, while perusing the ads in the magazines (one would hope 73), he has read an article or two about packet radio. He's heard that packets are relayed all across the country. How does this work? He assumes that a station broadcasts the message

and a local repeater will pass it along. "How do I get started in this? It sounds a whole lot cheaper than calling long distance!"

Let's deal with the second question first. I'll try to simplify an overview of packet radio in just a few short sentences. Purists may quibble, but I'll try to be accurate. To begin with, the "packets" of packet radio are not messages themselves, but discrete bundles of characters which may contain several kilobytes of information. The contents of a transmission may therefore be made up of one or many such packets. Each packet carries with it an address, the intended recipient. Now, if you are sending to the recipient directly, there is no need to repeat the information. But, if not, the packet is received by an intermediate station, held in a buffer, and then retransmitted, to be picked up by the next station down the line. This might be the recipient, or another repeater. Unlike voice repeaters, however, which simultaneously retransmit received information on another frequency, digital repeaters, or digipeaters, receive and transmit on the same frequency. The transmissions take place only af-

ter listening to be sure the frequency is clear, and many transmitters may swap in and out with packets, all taking turns. Isn't that nice? And no, it may sound cheaper than long distance, but all that packet switching can take quite awhile, so it ain't faster. Additionally, remember, this is still a hobby, so no business messages via packet, not even to this columnist!

All you need to get started is a VHF transceiver (we'll discuss that in a minute), some kind of terminal, which can be a computer or dumb terminal, and a terminal node controller, the packet equivalent of a modem. These come in various styles and prices, from ultra-cheap to ultra-sophisticated. There are even computer programs which can substitute for the TNC; our "RTTY Loop" disk collection has a few worth looking at.

Two references I can recommend are: *Digital Communications With Amateur Radio*, which can be purchased at your local Radio Shack, or ordered as a special edition from AEA Inc., P.O. Box C-2160, Lynnwood WA 98036; and *The Digital Novice*, by Jim Grubbs K9EI, QSKY Publishing, P.O. Box 3042, Springfield IL 62708.

I don't have current pricing information on either book, but they are both good, and cover the material in different ways. Be sure to mention "RTTY Loop" to them when you write—maybe it'll get you something, maybe not!

Now, as to the other question, that of building your own 2 meter transceiver. Are you sure you want to do this? There are some kits available. One source that has been around for years is Hamtronics, Inc., 65 Moul Road, Hilton NY 14468. They have various transmitter and receiver boards in the hundred dollar and up (and up) category. You may do as well, and grow less gray hair, if you look into used equipment in your area. Ham clubs, hamfests, and just asking around may turn up a bargain. Even an old handheld might be all you need to get onto a digital mode. For all I know, two days after this column runs, every ham in Houston will be calling you to offer help. Just hold your solder for a few days, and let me know what happens, okay?

Shifting gears, as we often do in this "Loop": Matthew F. Judge dropped me this question via the CompuServe network. "I was reading your column in 73, and was hoping you could answer what may be a stupid question. I am writing a new computer-aided dispatch system for my police department. As such, I would like to put our TDD system in the PC. Is the RTTY Baudot code the same as the Telecommunications Device for the Deaf Baudot code? I have not been able to find any difference listed. If there is no difference, could you point me towards some RTTY Baudot software (must be in Windows)?"

Where's the Beam?

Unobtrusive DX Gain Antennas for 60 thru 10
• Easily hidden • Install Fast • Fixed or Portable •

There's a 20 meter antenna with real DX punch hidden in this picture. You can't see it, and your neighbors can't either. But it works DX best: anywhere. How about a low profile 50-40-30 m. bander? Or a 2 element monobander for the attic? All easily fit the pocketbook. Priced \$29 to \$99.

Work DX without telling the neighbors

FAX (512) 647-9007

Well, the reason that you have not been able to find any difference between amateur Baudot and TDD Baudot is that there isn't any! After all, much of the early work in establishing the TDD standards was done by amateurs in groups like the Telephone Pioneers, working with discarded Model 15 and Model 19 teleprinters. The only major difference is that the tone pairs used in signaling on amateur AFSK and FSK circuits are different than TDD tones, which are based on telephone modem frequencies.

Any of the "TU-less" computer programs should work, as long as the proper interface to telco is provided. Again, there are several programs in the "RTTY Loop" collection you may be interested in. See the end of the column if you are interested in these materials, and good luck with this worthy endeavor.

Finally, something sentimental. Long-time readers of this column may remember my love affair some years back with the Motorola 6800 CPU. The father of the 6809, and grandfather of the 68000 series that powers Macintosh computers, this incredibly powerful computer never really took off. Well, here is a letter from John C. Delaive VE4YD of Winnipeg, Canada, who still has faith. He is running a system under OS-9, the multi-tasking, multi-threading operating system for

the 6800/6809 that predated OS/2 by a decade, with the original Stylo word processor, Dynacalc spreadsheet, and a RTTY program to boot! He offers assistance in locating boards or supplies for this system. Interested parties may drop me a line and I will forward the information to him directly. Thanks for the memory, John.

I have mentioned the "RTTY Loop" collections a few times. For those who came in late, I have four disks worth of programs, with collections #1, #2, and #4 being RTTY, packet, and amateur radio programs, and #3 the collection of archiving utilities. Each collection will fill a 3.5", 1.44 Mb disk, or appropriately more disks of lesser capacity. If you would like any or all of these collections, simply send me sufficient media (5.25" or 3.5") to hold the stuff (no need to format the disks), a self-addressed stamped mailer to return them to you, and \$2 in US funds for each disk enclosed. If you would just like a listing of all the programs, send a self-addressed stamped envelope to me and request the collection listing. Sure, I can send that to you via Email as well, on any of the usual networks. Send comments, questions, and critiques to me by mail at the above address, or on CompuServe at 75036.2501; America Online at MarcWA3AJR; or Delphi at MarcWA3AJR. I look forward to it! 73

PACKET & COMPUTERS

Continued from page 48

to get this info. Try to record the whole model number, and any revisions if you see them on the Printed Circuit Board or PCB. Record this information in the manual too, for easy access. Function means: What does the board do? Don't laugh, this may be necessary if you can't remember—and it happens! Finally, record the IRQ, I/O, DMA, and Mapped

Memory information so that when it comes time for a new board's configuration, you won't end up in a hair-pulling fit.

Next Month

We'll take a look at an interesting new product—using TCP/IP—that is a one-board (!) packet station. We're talking the whole station here, including radio. Talk about space saving. We'll also get a look at the "statistical" part of the survey information. 'Til then 73 de N1EWO. 73

Photo B. 16-year-old Jason McLaughlin KD6ICZ loves everything about ham radio, but his favorite activity is T-hunting. Why not introduce a young person to ham radio by inviting him or her to ride with you on your next hunt?

outline together."

The best writing, whether fiction or nonfiction, is done by people with firsthand knowledge of their subjects. Dave is well prepared to write a book that includes data encryption, bicycling, and T-hunting. "Cryptography has been an interest of mine," he said. "I wouldn't really call it a hobby, but I am a member of the American Cryptogram Association. I guess it was my exposure to codes in the military that intrigued me."

Writers develop their own favorite ways of clearing their minds, forcing concentration, and releasing creativity. "At the time that I wrote *TFA*, I was an avid bicycle rider," says Casler. "I would go on a long bicycle ride and think through a chapter, then come home and write it down."

Casler drew on his T-hunting experiences at Brigham Young University to complete his tale of high school ham adventure. "I'd been interested in ham radio for years, but it wasn't until I was in college that I did something about it," he says. "The club I was in had a lot of T-hunts. We thoroughly enjoyed them. I thought they were the greatest thing."

"We'd gather together on Saturday for the hunts. They would be on 2 meter simplex. We'd limit ourselves geographically. They weren't like some of the modern T-hunts that are

truly grueling events. The fox had to stay stationary and didn't have to transmit a whole lot. Everybody constructed five-element beams out of the *Handbook* to hang out the side of the car and hold up on a stick. I didn't have one, so I'd be either the driver or the navigator on a team. We'd drive all over town and take bearings based on the S-meter. The first team to find it won."

Young readers will have no trouble identifying with lead character Ben Thompson. "I tried deliberately to make Ben a decent, fairly responsible, but in most respects ordinary person," says KEOOG. "He's vulnerable, not always as convenient as he could be. His buddy Josh Adams NOMUX is much the same."

Early in the story, Ben meets Toby, a new student from Los Angeles who seems hard to get to know. Ben wonders if he can be trusted. "Toby took over the book," Dave admits. "I hadn't intended for him to be that prominent. I became fascinated by this fellow." Readers will be, too.

"Stealth" Publisher?

The Tompkins and Wall books are readily available from ham radio dealers and by direct mail from the ARRL (see Photo A). Cindy Wall often goes to ham conventions and is invited to give talks in Oregon

schools about ham radio and writing.

On the other hand, Casler's book is not being promoted by its publisher. You probably can't find it in ham stores. Fortunately, I noticed it in a 73 *Amateur Radio Today* ad for MFJ publications via mail order. You can order it by calling (800) 647-1800. Stock number is MFJ-3101.

When I asked if Ben Thompson might have more adventures in his future, Dave said, "Writing the book was a blast. I've thought about sequels. I've got two plots already worked out in my mind, using the same characters."

I hope MFJ soon realizes what an asset they have in KE0G and his book. It needs lots more publicity. I also hope that more elementary and secondary educators can be made aware of the value of ham radio fiction. All of the Tompkins, Wall, and Casler titles deserve prominent display in school libraries across the country. (Right, Carole?)

So if it's time to get a birthday present for a grandchild, niece, nephew, or any other young person who should learn more about ham radio, consider one or more of these fine books. But be sure to do your shopping early, so you'll have them in time to read yourself!

Next time a young person shows interest in your ham radio activities,

be sure to take time to give him or her some "show and tell." And when your club puts on a T-hunt, invite a youngster along (Photo B).

Tones for the Tiny T

Last month I reported that Ken Bauer KB6TTS was adding FM to his subminiature CW transmitter for 2 or 1-1/4 meters, described in May's "Homing In." Ken's modulator has

circuit (Point A).

The modulator circuit loads the oscillator, so order your crystal about 2 kHz higher than your intended output frequency. DC bias on D1, supplied by resistive divider R8/R9, fine-tunes the carrier frequency. Values given for these resistors are to be used as a starting point. Change them as necessary to put your T exactly on channel. As the

"Next time a young person shows interest in your ham radio activities, be sure to take time to give him or her some 'show and tell.'"

been successfully tested and it works perfectly with the Communications Specialists ID-8, reviewed last month. The entire hidden T, including the 9-volt battery, fits inside a small pill bottle or . . . well . . . use your imagination.

Figure 1 is the schematic for the added circuitry. D1 is a varactor diode, Motorola part number MM-BV809L. It changes capacitance as a function of the reverse voltage applied to it. This varies the frequency of the oscillator, resulting in FM. D1 connects through L4 to the crystal lead that was grounded in the original

battery voltage decays, some frequency change will occur, but it is not great enough to warrant a voltage regulator.

Most foxbox and IDer boards include keying circuits, so U1, Q3, R5, R6, R7, and C8 in the CW transmitter are not needed. Deleting them frees up about a third of the board space, giving plenty of places to tack down the modulator components. Connect the top side of R8 to the point marked Vcc on the original schematic. Vcc also ties to the positive battery terminal. The circuit ground of the tiny T goes to the NPN keying

transistor of your foxbox or IDer (gray lead of the ID-8).

Surface mount components are best, although you can squeeze 1/8-watt resistors into some locations. Newark Electronics carries the varactor diode. All other parts are available from Digi-Key Corporation. Boards and completed units are available from KB6TTS. For prices and availability, send a self-addressed stamped envelope to Ken at 2306 Turquoise Circle, Chino Hills CA 91709.

In addition to the ID-8, suitable tone and ID sources featured in previous columns include RaCon (July 1993) and TBOX (October 1991). Approximately 2 volts peak-to-peak audio is required for +/- 4 kHz deviation. Foxboxes are designed to drive microphone inputs of HTs and mobile rigs, so they include one or more dropping resistors in series with the audio level potentiometer (R9 and R10 in TBOX, for instance). Short these resistors or replace them with lower values to raise the audio voltage output.

Set FM deviation with the audio pot on the tone/ID source. A deviation limiter circuit is not included because foxboxes have constant output level. However, you may need to add a high frequency rolloff capacitor across R9 to round off square wave foxbox tones.

Ocean Challenge Follow-Up

This column deals with one of the best follow-up activities we've ever had in our ham radio class. When my 6th, 7th, and 8th grade ham radio students were selected to get involved with the Ocean Challenge project ("Hams With Class," June 1993) we had no idea what a fantastic fun learning experience it was going to be.

Bill Biewenga and Rich Wilson WA1BZE set a new sailing record on April 7, 1993, from San Francisco to Boston, around legendary Cape Horn, aboard their 53-foot trimaran *Great American II*. Today in Boston, 69 days 19 hours out of San Francisco, the *Great American II* lies quietly between the New England Aquarium and Long Wharf, at a clipper ship terminal from the 1850s.

This incredible voyage was of special interest to us since my students were able to make actual contact with Rich via ham radio. The youngsters were positively mesmerized by his accounts of dolphin and whale sightings. You could hear a pin drop in our room as Rich described the flying fish that hit him in the face when he lowered himself overboard to remove some kelp from the hull. We were well organized by the second contact, with children at the wall map recording longitude and latitude readings, as the others stood by patiently with their prepared questions.

Rich explained to my kids that their dream was twofold: offshore, to challenge themselves in their chosen arena against the best; and onshore, to share their adventures en route with students and their families. As promised, it was arranged for Rich to meet with my ham radio students at the New York City South Street Seaport on June 10, 1993.

I am totally amazed at the amount of enthusiasm this trip generated in my school (Intermediate School 72 in Staten Island, New York). The 12 youngsters who actually contacted Rich were the first ones invited to meet him. I then ran several contests amongst my students to determine who else would be lucky enough to accompany us to the Seaport. The kids really went wild, bringing in all kinds of nautical and marine projects and reports.

On June 10th, 32 children and three parents accompanied me to meet with Rich Wilson in person. There was a canopy set up on board the *Peking* ship docked at Pier 17 in the Seaport in lower Manhattan. The weather was magnificent as we all proudly boarded the ship to have our much-anticipated live interview with someone who had just been a voice on the radio. The TV cameras were there, which added to the excitement.

The children sat on the deck in front of Rich as he enthusiastically conjured up the most wonderful images of his voyage for them. One child asked about the most beautiful sight Rich had seen. The response was that it was a hard choice, but that he had truly been

Photo A. Carole and the kids at the South Street Seaport in front of the *Peking*.

in awe at seeing a full double rainbow off the coast of Brazil. He also surprised the kids by telling them that he and Biewenga ate like pigs and kings in order to keep up their energy level. They consumed an average of 3,000 to 4,000 calories a day. They had lots of canned fruits and vegetables, and drank soy milk.

There were lots of questions about the relationship between the two crewmen. Rich explained that though they were best friends, they still had arguments. Living in a 12-foot-by-12-foot cabin, they learned to sacrifice their own egos for the team goal.

The children, of course, wanted to know about the scary things. Rich assured them that there were plenty of scary experiences. He said it both scared and fascinated him to think of the ocean beneath him being 13,000 feet deep. Many things amazed him, like the interconnection of things in na-

ture. Sand from the Sahara desert was found on their sails over 2,000 miles away.

The thing they both missed most was the contact with their families and friends. The first thing they did when they got back to Boston after their 15,300-mile voyage was to go out with family and friends for a big spaghetti dinner.

Of course, what made the children smile ear-to-ear was when Rich told them how very much it meant to him to speak with them on the ham radio. He said he took great heart in hearing firsthand how we were all rooting him on. His parting words to the kids at the Seaport were, "Keep dreaming your own dreams, and the day will come for you to go and live them."

There's no doubt that—thanks to ham radio—we were able to share in an extraordinary piece of history that we'll always remember.

Low Power Operation

Michael Bryce WB8VGE
2225 Mayflower NW
Massillon OH 44646

Imagine you're taking a solo trip to Hawaii in your Cessna 150. During your travels, you end up having engine trouble over the South Pole. Making an emergency landing, you prepare to walk out. All of a sudden the storm of the

century starts a blowin', glaciers are cracking, bronchitic sea gulls are coughing up green ice cubes. The blizzard's so strong you're being lashed by unsecured penguins. Just when you can't take any more, a giant crevasse opens up before you. Suddenly, a yeti lays his paw on your shoulder as your left leg drops off from frostbite. At this moment,

don't you wish you'd brought along your HW-8 and a small antenna tuner? A random wire fastened to a stack of frozen penguins would be great while you pound away on your straight key for help inside your snow cave. Low power is always better than no power.

But what about the antenna tuner? You can't get too much inside a Cessna 150, so you had better make it a bantam-size tuner. But, you want one that will match coax as well as random wires and oh yes, don't forget about balanced lines, too.

Well, I may have exactly what you need. It's a Super Tee tuner designed

by D. A. "Mike" Michaels W3TS, and it first appeared in the June 1992 *QRP Quarterly*. Mike based his design on the original work done by DJ2LR, published in the December 1974 issue of *QST*.

Getting the Parts

The best part of all is that Kanga US has a complete kit ready to go. As with all the kits by Kanga, you get a baggie full of parts. Of course, the box to hold it in is up to you. Bill Kelsey was kind enough to let me have one of these kits at this year's Dayton Hamvention. The kit comes with all the inductors required, as well as several feet of wire of differ-

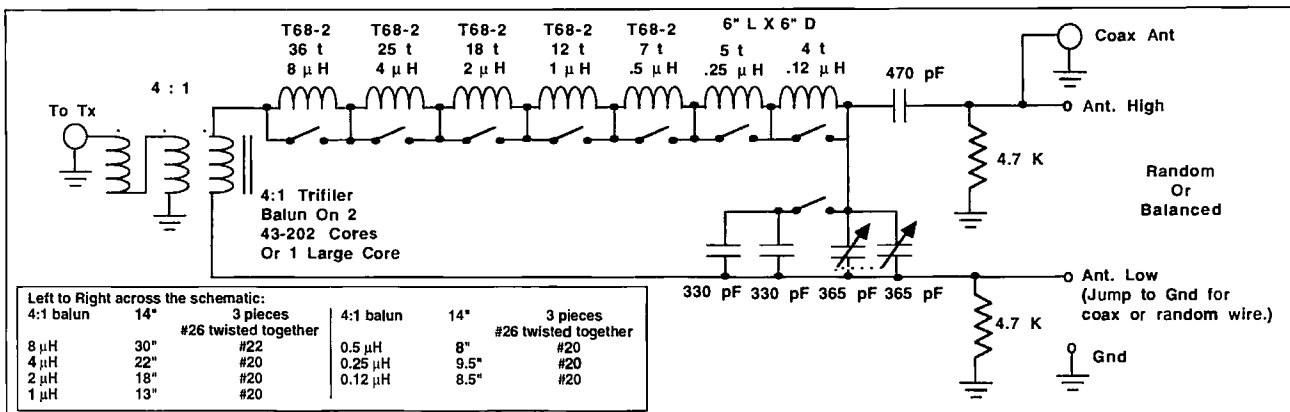

Figure 1. Schematic for the Super Tee antenna tuner.

Figure 2. Winding for the trifilar balun. The solid line represents the three wires twisted together. Use an ohmmeter or continuity tester to be sure you have the right end of each winding when you solder it into the circuit.

ent gauge. Also included is the variable capacitor (always a hard-to-get part), and the two-hole balun cores, also hard-to-find. Even SO-239 antenna connectors come with the kit (surprise!). The Kanga Super Tee antenna tuner is \$20 plus \$3.50 shipping from Kanga US, Bill Kelsey, 3521 Spring Lake Drive, Findlay OH 45840.

How It Works

The tuner operates as a low-pass circuit and does not have any false modes that present high circulating current.

Seven slide switches and seven separate inductors are used to get a wide range of inductance while keeping the "Q" high. By using separate inductors that are shorted out by the switches when not needed, the shorted turn effect (which would lower the Q) is avoided.

ed. This means all of your hard-fought-for QRP RF is going to the antenna and not into the tuner.

One of the improvements Mike made is raising the low side of the tuner above ground. This allows the tuner to be used with a balanced line.

Putting It Together

As with just about all Kanga kits, the instructions are very thin. In fact, with this kit they're almost transparent! Even though this is not a hard-to-build kit, it might be more than the first-time builder can swallow. Not that the kit contains zillions of parts but, as with all antenna tuners, most of the work is metal forming and mechanical assembly. Without a ready-to-use box, the builder has to install seven slide switches, and that's not an easy task. Slide switches are a pain in the butt to mount on a panel.

There is no PC board to stuff. All the parts go in as point-to-point wiring. A pictorial would have really been nice to see, but alas, there is none. There is a large pictorial for winding one of the balun coils. This coil could be a source of real hair-pulling frustration without the drawing.

All of the coils mount to the back of the seven slide switches. You have to wind several toroids for this project, too. The instructions give information on winding the cores. There is a list showing you what length of what size wire to make each coil. Looking over the in-

structions, I came across some text telling me some of the coils come pre-wound but may have too many turns on them. So, just remove what you don't need and use the core. It would have been a good idea to mark what pre-wound core was what. I don't know about you, but I can't tell what the core type is by looking at it. Looking back, I wonder what would have happened if I just used the pre-wound cores without removing the extra turns? More inductance, yes; a screwed up Super Tee tuner, more than likely not.

The Variable Capacitor

The twin-ganged variable capacitor must be isolated from ground. How to do this is up to you. Several ideas are presented in the instructions to head you in the right direction. In the olden days, an insulated shaft coupling would be easy to come by; today, it's a different matter altogether.

I used a hunk of Teflon to mount my capacitor. Plastic stock would work just as well, as would a piece of sealed wood. A small length of a Bic Stick (the pen) makes a very good insulated shaft to connect to the capacitor. I happen to have a panel bearing in my junk box, so I did not have to worry about the case eating up the plastic shaft. An old pot (a 1957 version—not the ones used today) may be used for a panel bearing—sometimes. No matter how you do it, you must insulate the capacitor before

the tuner will work. That includes both the rotor and the stator!

On the Air with the Super Tee

All you have to do to operate this tuner is to select the proper combination of inductance and capacitance, just like a regular tuner. But, instead of flipping through a range of inductance via a multi-tapped switch or roller inductor, you have to flip the slide switches on and off, selecting or de-selecting the inductance.

You do this by fully meshing the variable capacitor (max capacitance) and leaving open the switch to the extra 660 pF. Next, adjust the slide switches for a noise peak in the receiver. Peak for best noise with the variable capacitor, keeping it toward maximum capacitance. Finally, apply RF to the tuner and adjust the inductance and capacitance for the best match. By going for the noise peak first you should be fairly close to the final adjustment.

I'm not sure about flipping the switches on and off with RF applied, even with QRP power levels involved. To be honest, I've never been one to trust slide switches to begin with.

All in all, the Super Tee antenna tuner works quite well. Depending on how you end up building it, you'll find room for one in your Cessna 150. Of course, it will be up to you to find out if you can even stack frozen penguins before you start running wires to the tuner.

INTRODUCING THE UNIVERSAL M-400

A totally new concept in code / tone readers!

- A RTTY-reader and tone-decoder in one!
- Easy to read two-line 40 character LCD.
- No computer or monitor required.

- Baudot
- SITOR A/B
- ASCII
- Swed-ARQ
- FEC-A
- FAX
- POCSAG
- GOLAY
- ACARS
- DTMF
- CTCSS (PL)
- DCS (DPL)

Forget the limitations you have come to expect from most "readers". The self-contained Universal M-400 is a sophisticated decoder and tone reader offering an exceptional range of capabilities. The SWL will be able to decode Baudot, SITOR A & B, FEC-A, ASCII and SWED-ARQ. Weather FAX can also be decoded to the printer port. The VHF-UHF listener will be able to copy the ACARS VHF aviation teletype mode plus GOLAY and POCSAG digital pager modes. Off-the-air decoding of DTMF, CTCSS (PL) and DCS is also supported. The M-400 can even be programmed to pass only the audio you want to hear based on CTCSS, DCS or DTMF codes of your choosing. The M-400 can run from 12 VDC or with the supplied wall adapter. The American-made Universal M-400 is the affordable accessory for every shortwave or scanner enthusiast.

Only \$399.95 (+\$6 UPS).

Inexpensive 900 MHz System

Last month we described the Fort Wayne, Indiana, crossband ATV repeater. In order to avoid many of the problems which can arise when building an in-band ATV repeater, the Fort Wayne group chose to put their output on the 900 MHz band. The 900 MHz band was chosen over the 1200 MHz band because inexpensive downconverters from a wireless video system called the Gemini Rabbit were readily available at many stores at a very reasonable

price (usually under \$50 for both a transmitter and a receiver, complete with cables, power supplies and an A/B switch). In fact, a number of stores sell just the receiver by itself at a substantial savings.

However, as with any bargain, there is a catch. These little black boxes (see Photo A) come with built-in whip antennas that need to be removed and replaced by connectors. Jim Pliett K9OMA of the Fort Wayne group would like to share some of his modifications that allow these units to perform well for amateur TV use.

Modifying the Rabbit

To add an antenna connector to the Rabbit receiver, you must first re-

Photo A. The Gemini Rabbit wireless video system consists of a tunable TV transmitter and receiver that operates on the 900 MHz band. (Photo by Jim Pliett K9OMA.)

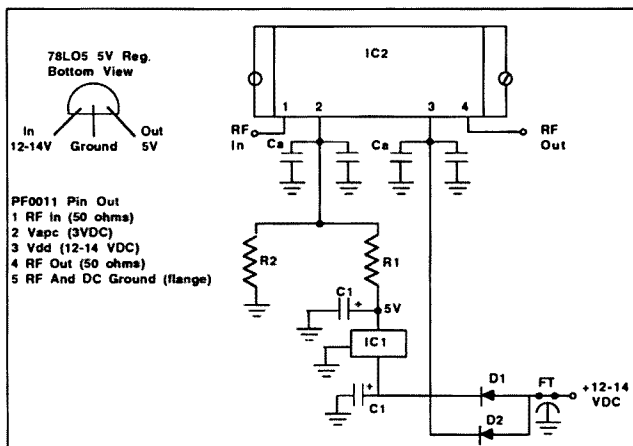

Figure 1. The output power of the Rabbit transmitter can be increased to over 5 watts through the addition of this Hitachi PF0011 linear hybrid MOSFET amplifier module. (Drawing courtesy of Bill Olson W3HQT of Down East Microwave.)

Photo B. To add an external connector to the receiver, remove the shield cover as shown. (Photo by Jim Pliett K9OMA.)

Photo C. Adding an external antenna connector to the transmitter. (Photo by Jim Pliett K9OMA.)

move the metal cover directly over the area where the whip antenna is located (see Photo B). You'll need a large soldering iron (100 watts or more) to remove this cover. You can also use a small pencil torch which can be obtained in most discount tool stores for around \$5 or so.

Once you have the cover off, unsolder the capacitor which is hooked to the whip antenna. Using a pair of pliers and a screwdriver, remove the two small screws and nuts holding the whip to the backplane. You will have to determine the type of connector you want to install on the back of the Rabbit's case (usually a female BNC or F-connector). In any case, try to find a connector that threads from the rear. It's much easier to install when you can insert the connector from the outside (with the nut on the inside).

Once the connector is installed,

just solder the capacitor to the connector's center pin, resolder the lid back on and you're ready to receive. Follow the same procedure to install a connector on the Rabbit transmitter (see Photo C).

Tune-Up

The receiver has a tuning control that covers most of the 900 MHz band. Once it's hooked up to an external antenna it appears quite sensitive when tuning in the ATV repeater. With the small size and shielding, it may even work well as an antenna-mounted downconverter if the tuning control lines are "remoted" (thereby eliminating most of the coax loss).

After you remove the lid of the transmitter unit you'll find a small potentiometer near the whip antenna. Adjustments to this pot will vary your output power from around -2 dBm to about +6 dBm (about 4 milliwatts). Although this is certainly not a real powerhouse, it does transmit an excellent quality picture and subcarrier audio. Since it is not crystal-controlled, it may drift in frequency somewhat, so try to readjust the transmitter frequency control whenever the drift becomes too much.

For those of you who want some real power on the 900 MHz band, there is an easy way to up the Rabbit's output to over 5 watts.

High-Power Rabbit

Bill Olson W3HQT of Down East Microwave offers a linear hybrid MOSFET amplifier module (902-928 MHz frequency range) that should take the low power (4 milliwatt) signal from the Rabbit transmitter and bring it up to over 5 watts (see Figure 1). In contrast to many power modules that were originally designed for the cellular telephone service, this Hitachi brick is very linear (perfect for AM-

modulated amateur TV). It runs off of 12 VDC and draws about 2.5 amps at full output power (approximately 10 watts) when driven with 10 milliwatts.

You should mount the Hitachi power module onto a heat sink (use a layer of thermal compound for efficient heat transfer). Be careful not to overtighten the mounting screws or you could crack the module's substrate. The output gain is adjustable from 30 to 50 dB with an external control voltage (3 volts nominal); however, the 30 dB gain setting offers the best linearity. Each of the two voltage inputs needs to be bypassed to ground through parallel capacitors, as shown in Figure 1.

Down East Microwave (Box 2310, RR1, Troy ME 04987; telephone: (207) 948-3741) offers the PF0011 module for \$65 + \$3.50 s/h, and a

blank PC board that can be used with the module for \$8. They also have a complete kit which includes the PC board and all components for \$95 (model #3310PAK).

This linear amplifier is easy to build and mates well with the power level of the Rabbit transmitter. It is also a good choice for any transmitter circuit you may want to amplify (as long as you don't exceed 10 milliwatts into the brick).

I hope that the easy availability of the units described in this column helps spur some more activity on the 900 MHz band. Even though we are sharing the band with an ever increasing quantity of consumer and commercial users, it's still a very effective band for ATV.

Thanks to Jim Pliett K9OMA and Bill Olson W3HQT for the information presented this month.

10 GHz Operations Wideband FM and SSB

I have been asked numerous questions concerning 10 GHz operations, questions about everything from simple, easy-to-build systems to the more complex methods. The easiest to build and least expensive are the wideband FM systems. The least expensive types of these often use converted burglar intrusion alarms. At the other extreme are the SSB rigs that require expensive microwave hardware.

There are advantages to each mode. The primary difference depends on your luck finding equipment at a reasonable cost. In the case of the wideband, there are several outlets from which useful hardware can be obtained. These include many of the commercial burglar alarm companies that are replacing microwave units with newer devices. Check with your local alarm company to see if they will part with any of these gems

for little or nothing. They operate on 10.525 GHz, and can be moved down to 10.250 GHz by a simple screw adjustment.

If you are unable to locate surplus units, one alternative would be to buy from a vendor like SHF Microwave Supply, 7102 W 500 S. La Porte IN 46350. They stock both new and used units ranging in price from \$20 (for used) to \$65 (for new varactor-controlled units). These were not intended for communication purposes but they adapt quite nicely.

Varactor vs. Non-Varactor Systems

Having a varactor frequency control system is just like having a variable capacitor in the circuit for frequency adjustment. Usually, capacitance is adjusted by varying the control voltage from zero volts to +10 volts. (The Gunn diode is held constant at 10 volts). Diodes that work in this voltage range are best. They will give you about 60 MHz of frequency adjustment. This best case scenario is achieved using the very fine MA-COM GUNNPLEXER—the standard for excellence.

By comparison, the unit with varactor control available from SHF gives about 15 MHz of frequency control. The varactor makes the tuning operation quite easy compared to a non-varactor-controlled system.

In a non-varactor-controlled system, tuning is achieved by varying the frequency adjustment screw to the exact frequency you desire, just like with varactor units. You need to use a frequency meter or wavemeter. This adjustment is made with the Gunn voltage (normally +10 volts) set to about 9 volts. Then, after you have calibrated the set screw frequency adjustment, you can vary the Gunn voltage up and down from about 8 to 10 volts for a fine frequency adjust control. As the voltage nears 8 volts, some diodes will drop out of oscillation. This voltage limit varies among Gunn diodes. You will have to find the adjustment and voltage range to suit your system. The range depends on cavity adjustment and so many other factors that I simply can't list them all here.

Here's an easy method to remember: Find the lowest voltage your unit will work at reliably. Set the mechanical adjustment screw to approximately mid-range with respect to frequency difference. Remember, frequency is not always linear and may be more affected at one end of the voltage range than the other end. Usually frequency changes more at the high end of the

adjustment. I have observed about 5 MHz of adjustment using this method of voltage tuning on a typical 10 to 50 mW Gunn diode system.

The premium units to use are varactor-controlled systems, those with both a Gunn diode and a varactor diode in the oscillator cavity. They are the easiest units on which to set frequency—and they make wideband operation quite easy compared to the burglar alarm units. The key difference is cost, from about \$20 for a burglar alarm unit to something closer to \$250 for a MA-COM GUNNPLEXER cavity. For a cost somewhere in between you can home-brew a Gunn cavity with some brass waveguide and a lot of patience.

I have had Gunn diodes available for several years, including both 50 and 100 mW devices. The high power devices are finally all gone but a few 50 mW devices remain. I am still searching for a batch of varactors to facilitate new cavity construction. Varactors have been quite scarce on the surplus market, halting home construction projects in this area. Recently I obtained a small quantity of varactors and they did not test out to be wideband devices. I realized only about a 5 to 10 MHz frequency adjustment range—disappointing, but they worked. I will continue to keep my eye out for more suitable parts. I haven't spent too much time trying to pur-

QSO Tutor®

Study Aid for the Amateur Radio Exams

Mac
IBM

Now Available,
New No-Code
Question Pool

- Runs on IBM compatibles or Macintoshes
- Programs are available for Novice, Technician, No-Code Technician, General, Advanced and Extra Amateur class exams as well as Commercial Radiotelephone and Commercial Radar Endorsement. Each program sold separately.
- Work with the entire question pools, or study questions automatically selected by the program from your weakest areas.
- Questions current as of July 1993
- Includes full screen graphics, explanations on appropriate questions and, on the IBM version, a pop-up calculator.
- Logs multiple study sessions and allows resuming at a later time. Returns to review missed questions if desired.
- Creates randomly generated sample tests on-line or printed with graphics on Epson/IBM or Macintosh printers.
- Public Domain Morse code tutor is included on request at no extra charge.

chase the components new, as I am trying to put together a "bargain basement" unit for wideband FM.

10 GHz SSB Operations

Operation on SSB—compared to wideband FM—demands a totally different type and complexity of circuitry. You could use these units for wideband FM but there is no reasonable benefit. The SSB systems will support narrowband FM just as easily as SSB and the improvements are remarkable, partly due to reduced bandwidth and frequency stability. Any time you

decrease the signal bandwidth you obtain a marked increase in distance and apparent power capabilities. For instance, take a 10 mW wideband unit and a 100 microwatt SSB system for comparison. On a path of about 150 miles during one of the the ARRL 10 GHz contests, we were unable to make contact with wideband FM using a 20 or so inch dish for the wideband FM system. With dish gain of about 25 to 30 dB, plus the 10 mW power input, we produced output power (ERP) of about 1 watt.

Now, for comparison, the SSB sys-

tem was a basic brick oscillator (with high frequency stability) and a mixer driven by a 2 meter FM handie-talkie for the IF system. This combination of components produced about 100 microwatts of power at 10 GHz. The antenna used was a 15 dB horn, and a reliable readable contact was easily made over this same 150-mile path. This narrowband system was operating at a fraction of comparative power output and some 15 dB difference in antenna gain, but the lower power and system gain still made the contact. The prime difference? Higher frequency stability was a factor, to be sure, but the most important factor was reducing the bandwidth from 75 kHz or so to 5 kHz deviation. A further improvement could have been made with SSB compared to narrowband FM, had SSB gear been available on this borrowed 10 GHz system.

Improved SSB stations usually do not operate on that low a power level, but great results can occasionally be found. Higher power stations may include TWT amplifiers (10 watts power output) feeding a 30-inch dish with some 35 dB gain, making a very formidable system. Lower power stations with solid-state amplifiers like the ones discussed last month are also used for power output in the 1/4 to 2 watt range. A 1/4W amplifier conversion from surplus material was also discussed in this column in the

September 1992 issue of 73.

High power and frequency stability alone do not make a station—other equipment is required. Each added component adds to system cost. You need to add mixers, microwave relay switching, receiver low noise preamplifiers, and still package this in something other than a 50 caliber ammo can. (Although I still use ammo cans when I can find them.) Cost-wise, a typical 10 watt TWT amplifier in working condition is priced at about \$200. The mixers can cost upwards of several hundred dollars for new commercial jobs, but surplus units can be obtained for about \$50. The microwave relays of the SPDT variety (four required for full switching applications) cost about \$30 each. The receive low noise preamp costs about \$80 for a home-brew unit.

The local oscillator can usually be found in one of two forms. One is a home-brew, similar to one recently described in QST by Zac Lau. This unit consisted of a crystal oscillator multiplier that used several GaAsFETs for microwave multiplication to the required injection frequency. The other popular form of device is the famous "brick" oscillator that appears from time to time in surplus. Zac designed his home-brew unit because of the low availability of brick type oscillators. I have to admire his well-thought-out design. I haven't priced out his compo-

How To Get Started In Packet Radio

Enter the exciting world of **packet radio** today with *How To Get Started In Packet Radio*. Dave Ingram, K4TJW, wrote this beginner's guide to **packet radio** in an

easy-to-understand manner. It starts with a non-technical description of packet radio, followed by chapters that include getting started, setting up your station, networks, BBSs, portable and high-frequency operation and even a *Packet Radio Equipment Survey*. There's also an appendix that includes circuits for interfacing equipment. **Join the most exciting and rapidly growing area of ham radio today!** Order your copy of *How To Get Started In Packet Radio* book for only \$9.95! CIRCLE 121 ON READER SERVICE CARD

nents, but I figure they cost around \$100, using a good junk box to hold cost down. That is competitive with the brick systems which cost \$50 each and require that an additional \$20 oven-controlled crystal be ordered from International Crystal for phase-lock operation. Again, this is just a price comparison of different systems.

The cost breakdown on the receive low noise preamp is as follows for a two-stage GaAsFET amplifier, with 18 dB gain and NF of about 2.5 dB: SMA coaxial connectors (female chassis mount) \$8, two MGF1402 FETs \$30, PC board w/chip res-caps \$20. Add some flashing copper for a box or container to house the amp and add the bias power supply and you add another \$10 to \$15 dollars to the amp's cost. Of course, this price can be greatly reduced by raiding a well-stocked junk box.

Well that's the overview on operation and system costs. There are many advantages and disadvantages to each and every system, not withstanding cost. These truths are not going to change. Narrowband operation methods far out-work wideband systems. Wideband systems are the least expensive. Crystal multiplier systems can have frequency accuracy problems, and that includes brick oscillators. But, if you can obtain a brick at a good price don't bother building your local oscillator. It's a lot easier to use a

brick than to build one.

Now, please be advised that I am biased towards the brick system and I use it extensively. I have invested lots of time in them and would rather fight than switch. Of course, what you do will depend on what you have available. I have acquired many extra bricks and will make them available to those interested, while supplies last. A 10 GHz brick is \$50 postpaid US only. A reset brick, set to 10.223 GHz for low injection (filters retuned), is \$65.

Please note that these units can be found at some surplus dealers for a lot less money. I have heard comments on prices ranging from \$100 at Dayton to \$5 from a flea market, so keep your eyes open.

Well, that's it for comparisons of different systems and components for 10 GHz. The basic mode of operation for most amateurs operating on this band is to first operate with wideband FM and then proceed to make many different modifications to their rigs, both commercial and home-brew. A natural transition to the more lucrative operation efficiency of narrowband modes is typical. During the last ARRL 10 GHz contest (September and October 1992), almost 90% of all 10 GHz contacts were made on SSB modes of operation. Wideband operation accounted for less than 10% of operation. Most of us bring out our wideband equipment but do not give it the same

Photo B. Bernardo XE2HWB at our hilltop operating position on the Isle De Guadalupe, Mexico.

attention that we used to. For instance, during the first contest back in 1986, all operation, without exception, was made using simple wideband FM burglar alarm units and some commercial MA-COM units.

Microwave Update '93

Just a reminder that the Microwave Update '93 Conference is going to be held September 24-25 in Atlanta. Papers to be presented at the conference include 10 GHz construction, waveguide fillers, 24 GHz operation, a single board 1296 transceiver, radio

astronomy, computer aided design, and microwave basics. This, as always, is expected to be a great program of microwave and VHF-UHF expertise. If you can go, you should. For details, contact conference chairman Jim Davey WA8NLC at 4664 Jefferson Township Place, Marietta GA 30066; (404) 998-6971.

is owned by Mexico and is located in the Pacific Ocean 155 miles west of Baja California and 350 miles south of Los Angeles. The 29th parallel bisects the island, placing it in grid locations DL08 and DL09. The main inhabitants of the island are thousands of chivos (goats). Human inhabitants reside on the southern half of the island and number around 50. They are primarily seasonal abalone and lobster fisherman, their families, and members of a small Mexican military detachment.

The main thrust of the expedition was to activate the island for the RS-GB-managed "Islands on the Air" (IOTA) program. The special IOTA designator for Guadalupe is NA-179. Participants were Jose Luis Ogawa XE2TT, Eusebil Morales XE2EAA, Felix Nunez XE2JNE, Bernardo Gonzalez XE2HWB (Photo B) and Jack Henry N6XQ. This is Jack Henry's account of that adventure:

Jose Luis did much of the planning, which involved negotiations with the Secretariat De Marine for prepositioning heavy and bulky items on the island. The generator, gasoline, antennas, tents, masts, beverages, etc. were transported by Naval frigate and stored at the island's marine base prior to our arrival.

At 1000 PDST on 14 May 1993, we departed Ensenada airport in a twin-engine Cessna. The flight was uneventful and in about an hour we were

circling the fishcamp. The flyover is the signal for the fisherman to load abalone and proceed to the landing strip which is about an hour's drive. After landing on the 6,000-foot runway, we had plenty of time to unload, take pictures and relax. Sure enough, about an hour later, a 1960 Jeep 1-1/4-ton truck appeared with what seemed to be about half of the fishcamp piled in back. The pilot placed a large tarp in the aisle of the aircraft and the fisherman transferred in more abalone than I had ever seen in my life. At about 1900 PDST all of the pre-deployed equipment, along with the gear we flew in with, was loaded into the truck and a small cargo trailer. The bumpy ride to the north yielded breathtaking views of the rolling volcanic hills, sheer drops to the ocean and an occasional sighting of a chivo herd.

Dusk signaled the arrival at our operating camp. We were in a little valley at the edge of a large forest of tall juniper and cypress trees. We immediately set up camp and erected a tribander. The first HF QSOs were made around midnight. HF conditions during the expedition were fair to very good.

Bernardo and I were the VHF operators for the expedition. The bands we operated were 6, 2, 223.5 MHz, 432, 1296 and 10 GHz. The first VHF QSO with the special call XF1G was with

W6OYJ in San Diego at 1550 on 15 May. Signals were good, but not super strong from this location, due to the rolling hills to the north of us. Morning and midday propagation were much better than the evening. We operated the VHF station on Saturday and Sunday from this site and moved the station to a 4,000-foot peak on Monday primarily to work 1296 and 10 GHz. The location was super. Phil W6HCC was setting his 10 GHz station in the San Bernardo mountains about 375 miles away. His signal on 10 GHz was S9 +40 dB. Subsequent 10 GHz contacts were made with N6CA, WA6CWM, WA6EXV, WA6CGR and WA6CDR. All were S9 +++ at distances better than 350 miles. W6HCC returned to his home QTH in Cherry Valley and bounced off the mountains to the north to work us with 5X5 peaks.

The best DX on 2 meters was with Dave WA6CGR, who was operating portable at Point Reyes, north of San Francisco, 700 miles distant. Dave was running 10 watts into a four-element yagi. Dave drove from Los Angeles primarily to attempt a 10 GHz North American record shot. There was high probability we would have made it if we had been at the higher location when Dave was there. (Dave was not available for the Monday attempt.)

All in all, there were 12 QSOs on

6 meters, 57 on 2 meters, one on 223, 17 on 432, six on 1296, and 10 on 10 GHz. Jack stated that if they had been able to operate on the mountain peak all three days, QSO totals would have tripled. Tuesday morning we packed up all the gear and headed for the fishcamp, where we would stay and wait for the flyover the next day for the return trip to Ensenada. The hospitality of the fisherman and their families was excellent. We slept in a one-room schoolhouse and our diet until the return was carne de chivo, frioles, and tortillas. The fishcamp had a pet chivo called "Chivo Loco" because it was mean and crazy. It would sneak up, chase, and try to butt members of our party with its long horns. We wondered how it escaped the dinner table.

The return flight was in a slightly larger plane and again uneventful. As an American, it was a real pleasure to work with the Mexican hams and be part of their culture for a week. They were most gracious and I was happy for the opportunity to participate in their DXpedition—de Jack N6XQ.

Well, that's it for this month. Next month I will describe a complete 10 GHz QRP SSB rig. As always, I will be glad to answer questions concerning this topic or other related VHF microwave material. Please send an SASE for prompt reply. 73 Chuck WB6IGP. 73

Mobile Operations

It's lots of fun to sit in front of a desk with a radio and talk around the world. It's also fun to yack with the locals on the neighborhood repeater from the comfort of your home. But America is a very mobile nation; the average driver goes between twelve and fifteen thousand miles a year! That's a lot of time spent in the car. And let's not forget all the other kinds of travel, including airplane, bus, train, bicycle and good ol' shoeleather. This month, let's take a look at installing and operating portable and mobile gear.

In the Pocket

There aren't too many hams who don't have walkies. At least, it sure looks that way at hamfests, where seemingly everybody has an HT attached to his or her body. HTs, which normally cover VHF and UHF, are lots

of fun. There's no installation required; you just turn the radio on and go. If you're walking around town, an HT lets you stay in touch with friends. If you have autopatch privileges, it can be awfully handy to make phone calls home or to a friend's house, as long as you remember to observe the rule prohibiting business communications. Oh well, you'll still need a real phone to order that pizza!

My primary concern regarding walkies is over the energy my head is absorbing from that rubber duck antenna two inches from my eyeballs. Although there's lots of controversy about it, the government has established safety guidelines for close-up RF exposure. 2.5-watt 2 meter rigs don't appear to pose significant danger, but I'd avoid using more power than that. Let's face it, even if you go to 5 watts, the difference of 3 dB at the receiving end is minimal, so why risk it? Besides, the high power output kills your battery a lot faster.

Another way you can help yourself remain safe is to limit your transmission time. RF exposure damage oc-

curs over a period of time, and is measured with regard to the average total power absorbed, not the peak power. So, if you're putting out, say, 2 watts, but only transmitting a quarter of the time, that's the same as putting out 0.5 watts continuously. Let's face it, most hams are too darned long-winded anyway! Listening more and talking less could only do most of us good.

Auto Mobile

If you use your walkie in the car, you will quickly find that the rubber duck antenna works very poorly when enclosed in such a metal cage. Unless you're close to the repeater, you're going to get lots of complaints from other hams that you're scratchy or dropping out. Reception probably will be noisy, too. With a rooftop antenna, though, it's a different story. Your range will increase dramatically. Also, you're pretty well protected by the metal roof and the increased antenna-to-body distance, so why not have all the power you can? Most of today's walkies put out between 5 and 7 watts when run on 13.8 volt car power. Be careful, though, because they get awfully hot while transmitting and can actually damage your car's upholstery (or your hand). It seems reasonable to assume the high heat reduces the overall lifespan of the radio, too. To avoid it, just don't transmit for long periods of time.

Many hams do, in fact, use their

walkies in their cars, mostly to avoid the expense of another radio. It makes sense, with today's mobile rigs selling for between \$300 and \$600. If you've ever tried it, though, you know that using your walkie in the car has some drawbacks. First of all, there's the low audio output. Most modern walkies are rather small, and their 200 mW outputs and tiny speakers were never meant to be heard over the noise of an automobile. Also, many HT's speakers are rated for less power than their audio amps actually put out! Under normal circumstances it's no problem because you don't listen to it at maximum volume anyway. But in the car, it's easy to turn it all the way up and leave it there. Sometimes, the result is a blown speaker and a trip to the repair center. And, oh yeah, a bill.

Pump It Up

Is there a way out? Sure. What you need is a separate amplifier and speaker. A bigger speaker alone probably won't do you much good because the rig's little internal amplifier just isn't likely to have the power to drive it. In fact, some speakers, particularly those intended for music reproduction, are exceptionally inefficient and can actually sound *softer* than the little one in the radio! So, an amp is called for here.

You can build one easily enough; many amplifier designs have been

LOOK WHAT'S NEW FROM DAIWA

.....Have You Seen These Great NEW Products

From Daiwa?.....

NEW

MH-200 - Lightweight, folding "personal stereo"-type single earpiece headset and flexible boom mic. Inline locking or momentary P.T.T. switch. Models for Kenwood, Icom, Yaesu and others.

ME-300 - Tiny in-the-ear headset with high quality tie-clip mic and inline locking or momentary P.T.T. switch. For Kenwood, Icom, Yaesu and others.

MD-400 - Compact, high quality gooseneck-type desk mic with P.T.T. and up/down buttons. Deluxe weighted di-cast base. Superb audio. Complete with attractive foam windscreens. Models pre-wired for Kenwood, Icom and Yaesu.

NEW

Compact, Full Duplex, GaAsFET Pre-amps!

DIA-25H - The perfect companion for dual band HTs while mobile! 25+ W kick on either band w/ 200mW to 6W drive for solid repeater coverage. From panel output meter, switchable, all-mode for CW/SSB.

DIA-50H - 50+W out on both 2 meters & 440MHz w/ 200mW to 15W drive. Plenty of power for those DX repeaters & reliable simplex operation. The perfect medium power dual band HT amp - and only from Daiwa!

DIA-80H - Heavy duty version, high power dual band linear amp. Full output (80+VHF, 60+UHF) from 3-25W drive - perfect for dual band HTs and mobile rigs! All-mode operation for CW/SSB, built-in fan for continuous-duty operation and more!

published right here in 73 magazine. If you're not so inclined, you can buy one, too. But why bother? There's an easier, cheaper way: Use your car stereo! If you have a cassette player, you can use one of those cassette adapters intended for portable CD players by plugging it into your rig's earphone jack. Just cut off the adapter's plug (which is stereo) and replace it with a mono plug, connecting the wires for the two channels in parallel. Or, use a stereo-to-mono plug adapter. You probably will have to turn your walkie's volume down quite low, and you may find that there's too much background hiss, or that you can't get the volume down low enough. In those cases, put a resistor in series with the hot lead. I haven't tried this, but I'd imagine that 100 ohms to 1k ought to do it. Experiment with it until you find a resistor value that allows you to set your walkie's volume about a third of the way up. Then, adjust your listening volume with the stereo's volume control. If you don't have a cassette player but do have an FM radio, they make adapters which actually are little transmitters you tune in on your car radio. They should work fine, too.

It's an Intermod World

Using a walkie in the car, you may run into a more serious problem than puny audio. You may find that your re-

ceiver gets trashed pretty badly in certain parts of town. If you live in a large city, you're almost certain to run into this problem. We live in an RF-saturated society, and most areas have lots of paging transmitters and public-service towers and such, emitting plenty of power 24 hours a day. Unfortunately, walkies' front ends are very small, and there just isn't room for big filters. Also, today's units (with the exception of the Radio Shack HTX-202) permit reception over 20 or 30 MHz, requiring wideband front ends anyway. Some HTs use voltage-tracking front-end filters driven by the microprocessor to track the tuned frequency, and that does help, but some don't employ such techniques. Finally, walkies are primarily designed for receiver sensitivity because they are intended to be used with those little rubber dummy loads. Intermod rejection must, by necessity, take a back seat.

Is there a way out? If you're sufficiently knowledgeable to build your own bandpass filter, that will go a long way toward reducing the garbage. Of course, you'll have to give up public-service-band reception. Another way out would be to design an automatic antenna switch which selects the roof antenna for transmitting and an indoor duck for receiving. As I mentioned before, reception with an indoor duck can be poor, but sometimes it actually works better than what you get with an

overloaded receiver. I remember once, in Miami, having the repeater disappear altogether, only to get it back once I switched to the rubber duck. It was a classic case of front-end overload.

The Juice

Oh yeah, I almost forgot—you're gonna need to power your walkie, too. Sure, you can use the batteries, but why use them up when your car can power the rig? Besides, as I mentioned before, you'll get both more transmit RF and more audio output on 13.8 volts. To properly operate your radio, the DC power supplied to it needs to be clean. Clean power in a car? Forget it! All car power is loaded with alternator spikes, ignition noise, you name it. Also, the voltage can go up and down, sometimes by up to 2 volts, as you drive faster and slower. Yuck! Many walkies have direct DC input jacks, suggesting that you can simply plug them into your cigarette lighter and talk away. You probably can, but you'd be wise to take a voltmeter and check the voltage of your car's electrical system first. If it's over 15 volts with the engine going fast, you've got a regulator problem and you can save yourself a radio repair bill by straightening it out before you plug the rig in. Also, if your car radio or stereo has lots of alternator whine (distinguished by its being audible

when the volume is turned all the way down), don't plug the HT in. Alternator whine consists of fast spikes which can be several volts or more. They are too fast to affect voltmeter readings, but they sure can ruin a radio. I've seen electrolytic capacitors, RF power output modules, and especially audio amplifier ICs ruined by prolonged operation on such spiky power. Fix the car first.

Some cars are very electrically noisy, but are not actually broken in any way; they're just made that way. If yours is like that, consider a power filter. Some rigs offer them as options. Or, you can buy a generic choke and capacitor-type filter at Radio Shack or an automotive sound-system dealer. You only need something under 2 amps, so a small one should be fine. Just be careful to connect it *after* a fuse, or you could be headed for real trouble. A friend of mine forgot to do that and suffered \$400 worth of damage to his car, including a blown alternator, when the filter shorted to ground. A 50-cent fuse would have prevented the whole thing. Heck, you don't even have to add your own fuse; just connect your DC lead to the fused side of your stereo's power line.

Well, there's lots more to talk about, including mobile VHF/UHF rigs and, of course, the ultimate mobile operation: HF. Until next time, 73 de KB1UM.

ID-8 Automatic Morse Station Identifier

Compatible with Commercial, Public Safety, and Amateur Radio applications. Uses include Repeater Identifiers, Base Station Identifiers, Beacons, CW Memory Keys, etc. Great for FCC ID Compliance.

- Miniature in size: 1.85"x1.12"x0.35"
- Totally RF immune
- All connections made with micro-miniature plug and socket with color coded wires attached
- CMOS microprocessor for low voltage, low current operation: 6 to 20 VDC unregulated at 6ma
- Low distortion, low impedance, adjustable sinewave output: 0 to 4 volts peak to peak
- Crystal controlled for high accuracy
- Transmitter PTT output (to key transmitter while ID is being sent): is an open collector transistor that will handle 80 VDC at 300ma
- Field programmable with SUPPLIED keyboard
- Confirmation tone to indicate accepted parameter plus tones to indicate programming error
- A programming is stored in a non-volatile EEPROM which may be stored at any time
- Message length over 200 characters long
- Trigger ID with active high or low
- Inhibit ID with active high or low: Will hold off ID until channel is clear of traffic
- Generates repeater courtesy tone at end of user transmission if enabled
- Double sided tape and mounting hardware supplied for quick mounting
- Operating temperature range: -30 degrees C to +65 degrees C
- Full one year warranty when returned to the factory for repair.
- Immediate one day delivery

Programmable Features

- Eight programmable, selectable messages
- CW speed from 1 to 99 WPM
- ID interval timer from 1-99 minutes
- ID hold off timer from 0-99 seconds
- CW tone frequency from 100 Hz to 3000 Hz
- Eight porch delay interval from 0 to 9.9 seconds
- CW or MCW operation

\$89.95 each

programming keyboard included

Notes from FN42

Ahhhhh! Another Field Day has been completed and a "good time was had by all!" As we were setting up a tower with a tribander on top, vertical antenna, wire antennas, VHF/UHF antennas, and satellite antennas, I was wondering why we go to all the trouble of setting it all up when in just a few hours (24 or so) we will be taking it all down again. But, after the first contact was made, that question seemed to answer itself. It's fun! Hopefully WS1A was heard and contacted by some of you. If not, well, there's always next year, and we are already critiquing this year's operation and making plans for next year.

A short FAX from David Horsfall, Ambassador to Australia, says that he has been very busy but will have some news for us next month.

Pay close attention to a packet message from Monk Apollo SV2ASP, Mount Athos. He provides us with the "real story."

Now, on to the news from around the world. 73, Arnie N1BAC.

Roundup

Ecuador Stuffed in the mailbox this past month was a copy of the program notes from radio station HCJB, Voice of the Andes. Since I know that some of you are also SWLers, you can also receive the same program schedules by writing: HCJB, Casilla 17-17-691, Quito, Ecuador, South America, and please tell them that 73 Amateur Radio Today sent you.

Israel Downloaded from packet originated by N1BEE @ KA1AZ as AMSAT News Service Bulletin 163.01: The Israel Polytechnical Institute will launch its first satellite, known as the Guerin-1, from the Baikonur space port in Kazakhstan, aboard a Russian rocket. Professor Guiora Shaviv, Director of the Space Research Department of the Institute said that the satellite will weigh about 60 kg. and will carry a packet radio Bulletin Board System (BBS) for amateur radio operations. This project involves the participation of 12 different Israeli companies. This satellite from "Technion," as the Polytechnical Institute is known throughout the world, was a project which began three years ago and will be placed in orbit as a secondary payload, along with a Russian satellite and another German satellite.

Please stay tuned for the AMSAT News Service bulletins for further details concerning the launch of this new amateur radio satellite.

The following report is from Arnold Samuels KH6COY: I must say that my last trip to Israel was FANTASTIC! I made contact with a group of hams in Natanya through Haim 4X6ZI. On very short notice, he called the hamdom of Natanya and the following hams showed up at a very pleasant meeting in the Hotel Goldar: Paul Gross 4X4UU; Haim 4X6ZI; Micha Klein 4Z4KM; Avner Hirschfeld 4Z4NH; Haylm Dentes

4X4DJ; Jose Cohen LU1HGA; Israel Berko 4X1OM; Haim Ken-tor (waiting for call letters).

They were really very hospitable and very enthusiastic to talk to an American ham. The group was eager to talk about ham radio in America and, since the Israeli license structure is patterned after ours, they also wonder if we are going in the right direction. It was a great experience to stand on 10,000 years of civilization. [Arnold Samuels KH6COY, 431 Bass Ave., Ocean Shores WA 98569]

Mt. Athos Downloaded from packet by Ron Gang 4X1MK, and sent to 73, originated by SV2ASP:

Greetings to all of you, DX friends all over the world.

I feel the need to communicate with you and to give you the real reasons, officially, why Mt. Athos is no longer heard on the air and when will it finally do so, because many rumors circulate and many things are written without containing a grain of truth.

I stopped broadcasting 15 months ago from Mt. Athos, because the ARRL has officially recognized the illegal broadcasts of the German ham Drobni-ca Baldu DJ6SI. I have in my hands all the legal documents which prove the fraud, and those recognizing the illegal broadcasts of the said ham.

This fact has caused a lot of upheaval here on Mt. Athos, as well as disgust, because it is against the articles of the Charter on the basis of which the Monastic Community is governed, and which has been respected for over 1,000 years, and which (Charter) has been respected by all, even the most cruel invaders.

The ARRL's taking this particular attitude allows—on purpose—time to go by and considers it a given fact. ARRL members spread the rumors that they will have Mount Athos removed from the DXCC countries list because it is no longer available on the air.

Dear Sirs: Mt. Athos is ready and waiting for the ARRL to live up to its responsibility and rise above interests and ulterior motives and cancel the illegal broadcasts of DJ6SI, so that Mt. Athos will be once again heard on the air.

Other rumors circulating about Mt. Athos going on the air again are totally misleading. They aim at placating the decent hams of the world who justifiably wish to establish contacts with Mt. Athos, the sole—on a worldwide scale—Monastic Christian Center with its rich history and its current growing presence, so they can acquire its coveted QSL.

I truly regret, dear friends, the way things have developed, but as a rationalist Orthodox Monk living here on Mount Athos, this locus of prayer and meditation, I cannot accept what has happened and what the ARRL continues to embrace with its official support.

I have faith in God that soon the correct solution will be provided by the ARRL and that this way I will once again join you on the air.

I send you my best wishes from Mount Athos.

God Bless You. Apollo, Monk, SV2ASP @ SV2DXC.TSL.GRC.EU. [Monk Apollo, Dochiariou Monastery, Mount Athos, GR-63087 Greece.]

Russia Downloaded from packet originated by Andy RW3AH: Only quite recently packet radio received a legal status in this country. But still we enjoy no expected "Big Bang" growth of this kind of communication. Yes, those who had a strong desire and could find money to buy themselves decent equipment are now already gaining their won experience. For the last three years, however, the number of packet radio stations increased very insignificantly, to say nothing of BBSs. This situation is certainly due to the general stagnation in our economy, though there is some light at the end of the tunnel.

At the end of 1992, Russian Amateur Radio Emergency Service (RARES) began developing a new local VHF packet channel on 144.650 MHz. The development of packet radio is going so fast that the brightest idea of amateurs is to set up a global packet radio network. TRANSPAK was started! Many organizational problems were overcome along the way. In a short span of time, we did as much as we could have done in the previous five years or longer. On May 4, 1993, we effected the first packet radio connection between Moscow (RW3AH) and New York (WA2NDV). Now we have a link with the American continent and Europe operating 24 hours a day!

This experimental link operates at 300 and 1200 baud (AX25). Today, we are able to communicate in real time with nearly all the continents. Constant forwarding with the U.S. is going fine.

We wish to express our special thanks to Frank WA2NDV without whose help and cooperation this project would probably still be on paper and not on the air. We also thank N2MH, WN9T, NT2X, RV6HY, and the teams at UZ3AWO and R3ARES club stations. [Andy RW3AH/WL7AP] @ R3ARES. #MOS.RUS.EU.]

Switzerland News taken from the International Telecommunication Union Press releases: Working Party 8A, chaired by O. Villanyi of Hungary, met in Tokyo, 13-22 January 1993, and approved six new draft recommendations on: cordless telecommunication systems; personal radio systems and digital short-range radio; future amateur radio systems, disaster communications in the amateur services; use of amateur services in developing countries; and frequency-sharing criteria in the amateur services. [No mention was made of what the recommendations said.—Arnie]

Future meetings known to include amateur radio working groups are: Study Group 8 on 26 October and 21-25 March 1994 in Geneva for mobile, radiodetermination, amateur and related satellites services; Working Party 8A 27 October to 5 November in Geneva covering land mobile service, excluding FPLMTS; amateur and amateur satellite services.

Task Group 8/2, chaired by P.L. Rinaldo (USA), met in Boulder, Colorado, 19-23 April 1993, and was attended by participants from various fields. They reached a common understanding about the situation of wind profiler radars and other services which might

have interferences to or from the wind profiler radars. The meeting produced the following results: one preliminary draft on technical and operational characteristics; four preliminary draft elements of the report to the Radio Communication Conference concerning general subject matters and candidate bands around 50 MHz, 400 MHz, and 1 GHz.

The Africa TELECOM 94 Exhibition and Forum will be held in Cairo, Egypt, from 25 to 29 April 1994. The Forum will be held under the theme: "Integrating Africa Regionally and Globally—A Challenge for Telecommunications and Development." For further information contact: Mr. Tom Dahl-Hansen, Executive Director, TELECOM, or Ms. Suzan Hee-Sook Lee, Project Manager, Africa TELECOM 94, ITU, Place des Nations, CH-1211 Geneva 20, Switzerland.

HONG KONG

Phil Weaver VS6CT
Flat 39C Two Park Tower
1 Kings Road
Hong Kong

As with everything else in Hong Kong, it can take an awful long time to get things done when it comes to recreational activity, as business always takes the front running when it comes to people's time, and as a result many of the planned improvements to amateur radio in Hong Kong, such as an extra repeater, renewal and installation of new beacons, packet cluster for ELARCS, and many other interesting projects which your committees are trying to implement, are slowly progressing. As most of you know, ELARCS has at last got its cluster up and running on 144.500 MHz, and we hope to shortly have a node up with the repeater so that the coverage can be improved and perhaps even get into Macau. Other improvements are in the pipeline, and we hope that 1993 will see many of these completed.

One of the topics currently being discussed by the H.F. Committee of the Radio Society of Great Britain (RSGB) is the question of access to the HF bands (below 30 MHz) without the necessity of a Morse qualification. Such a license would be referred to as a "code-free license." The RSGB tells us that amateur radio is controlled internationally by the regulations set by the International Telecommunication Union (ITU), which is an agency of the United Nations. They add that the current ITU regulations require that radio amateurs operating at frequencies below 30 MHz demonstrate their proficiency at sending and receiving Morse code, though the speed and nature of any test is not specified. The RSGB wishes to consult as widely as possible and seeks input on the question of a code-free license from any radio amateur or listener, whether they are for or against the idea of such a license. You should send your views, opinions and comments to: The HF Committee, c/o RSGB HQ, Lambda House, Cranborne Road, Potters Bar, Herts. EN63JE, United Kingdom. Letters should be clearly marked "Code-Free License" on the bottom left-hand corner of the envelope. Since Hong Kong is still a territory under the jurisdiction of the U.K. on international matters, at least until 1997, amateur radio here basically still follows their lead.

Finally, I would like to extend an open invitation to any of our readers that they are interested in a visit to the Maritime Rescue Coordination Centre located on the roof of the Rumsey Street Car Park Building in Sheung Wan to see the investment that the Hong Kong Government has made in the field of Communications associated with the implementation of the Global Maritime Distress and Safety System, they will be made very welcome. Please call Phil Weaver on 543 5558 during office hours to make an appointment.

Regards and 73 from "China Town."

MONACO

Daniel Plett 3A2LZ
B.P. 349
MC 98007
Monaco

Monaco hams quite often get asked the same questions from many U.S. hams. Here are some of the questions and how we'd respond.

1. Are there many active hams in Monaco? There are about 50 licensed hams with about 12 of them being fairly active on an international scale.

2. Is anyone active on CW, RTTY, AMTOR, packet, SSTV, etc.? One Monaco ham, by himself, does about 1,500 QSOs a year, mostly on CW, and most others do at least some. There are three or four equipped for RTTY but only one active right now. No one is currently active on AMTOR or packet.

There are a few equipped for SSTV, but no one is regularly active.

3. What about a DXpedition? There is no problem getting a reciprocal permit. The big problem is finding a place to operate. Monaco is extremely small and crowded and doesn't have much space for portable operation. Only one or two of the most expensive hotels allow antennas and radio activity. Many visiting hams in the past have abused their privileges, broken laws, and invoked the ill will of local hams. Most portable/mobile operations from Monaco end up being illegal one way or the other, and their contacts cannot be counted for DXCC credit.

4. How about a sked? Most Monaco hams are quite pleased to work U.S. hams, but don't usually make skeds. There are three main hindrances. The surrounding mountains have at least a 30 degree elevation, making low-angle radiation difficult. Most of us are limited to multiband vertical antennas. The 100 watt power limit makes it difficult to be heard through the rest of Europe. Here are two hints: 1) Think about local times. Most of us are working folks who have to keep somewhat civil hours. 2) Try long-path. Some U.S. hams check in quite easily to European DX nets this way and we do have low-angle radiation to the U.S. via long-path.

That's all for this time. If any of you have more questions, other than what I have covered, please contact me at my address, or pass the question to Arnie at 73 and he will get it to me. 73 to all.

Why buy a TNC?

PC HF FAX + PC SWL \$179.00

SPECIAL COMBINATION OFFER

For a limited time, if you order PC HF FAX \$99 (see our other ad in this issue), you can add our new and improved PC SWL 3.0 for \$80.00 instead of our regular low price of \$99.00.

PC SWL contains the hardware, software, instructions and frequency lists needed to allow you to receive a vast variety of digital broadcasts transmitted over shortwave radio. All you need is any IBM PC or compatible computer and an SSB shortwave receiver. The product consists of:

Demodulator
Digital Signal Processing Software
200 Page Tutorial Reference Manual
World wide Utility Frequency List
Tutorial Audio Cassette with Samples
PC SWL automatically decodes Morse code, RTTY, AMTOR, SITOR, NAVTEX and ASCII.

PC SWL lets you tune in on world press services meteorological broadcasts, ham radio operators, coastal shore stations, aviation telex and much more digital action on the shortwave bands. Why pay for another expensive box when a simple interface and your PC can do the job?

ADVANCED FEATURES:

Tuning Oscilloscope
Digital Waveform Presentations
Auto Calibration and Code Recognition
Continuously Tunable Filter Frequencies
Variable Shift
Adjustable CW Filter Sensitivity
Unattended Capture and Printing
Integrated Text Editor
Integrated Log and Database
Shell to DOS applications
Seamless Integration with PC HF Facsimile

Ideal for SKYWARN and A.R.E.S.

Now you can do something about the weather

The ULTIMETER® II Home Weather Station protects your equipment, helps you alert others to dangerous weather extremes

This ultra-reliable Weather Station is your first alert to changing local weather conditions. gives you up-to-the-second data to transmit on SKYWARN and A.R.E.S. networks.

The ULTIMETER II tells you when high winds threaten so you can crank down your tower and safeguard other equipment. You get over 20 weather functions vital to ham and other homeowners, including high/low temperature readings with pre-set alarms that help you plan your day, guard against frostbite, protect plants and people.

The ULTIMETER II's unique low-impedance wind sensor (patents pending) resists RF, improves reliability and shows speed and direction simultaneously. Comes with 40 ft. cable.

HOME WEATHER STATION...only \$179

Over 20 Weather Functions including:

- Wind Speed and Direction • Temperature • Chill factor • Alarms • Highs/lows/times / dates • Metric / English • Quick-Mount (no tools) masthead mounting • Fast, easy "Point & Plug" direction calibration • Optional self-emptying rain gauge with lifetime warranty • Serial output for optional logger • 30-day money back guarantee • One-year warranty

SavantTM
...because knowledge is power!

A Packet Radio Program for the Macintosh®

- Multiple simultaneous connections, each in its own window.
- Change "channels" by simply switching windows
- Simultaneous transmission and reception of packets in every session window. Savant is smart enough to route the incoming information to the right window.
- Written specifically for Macintosh (not a port from DOS)
- Implements the full Mac user interface, including:
 - Scroll back buffers in session windows
 - Edit menu with Undo, Cut, Copy and Paste commands
 - Saving and Printing of all or any part of a session window
 - User re-sizeable split windows
- Icons and fields in each window display the connection's status
- Packets outstanding and sent, retries, round trip time
- Stations Heard window displays the last 64 stations heard, and continuously updates the list.
- Monitor window decodes and shows all packet traffic
- Compatible with any TNC that implements KISS mode - AEA, Kaniotics, MFJ, etc.
- Fully compatible with the PacketMac modem from Sigma Design Associates and SoftKiss from Aaron Wohl
- System 7 compatible, 32 bit and cache clean

Demo version available! Call us for details.

SEPT 8-16

KIOWA, KS The Salt Plains RC will operate WA0HH/W100CS, to commemorate the 100th Anniversary of the opening of the Cherokee strip land rush into Oklahoma. Special QSL by #10 SASE. Frequencies: +/- 20 kHz, 3.900, 7.235, 14.250, 21.325 and 28.500. Contact *Kiowa Cherokee Strip Centennial, 717 Coats, Kiowa KS 67070.*

SEPT 10-12

NORWALK, CT The Greater Norwalk ARC will operate KA1OFN Sept. 10 2100Z-2100Z Sept. 12, to celebrate the 17th annual Oyster Festival and the 125th Anniversary of Sheffield Island Lighthouse. Operation will be in the lower 25 kHz of the General 80, 40, 20, and 15m phone subbands, and the Novice 10m phone subband. For a certificate, send QSL and SASE to *Greater Norwalk ARC, c/o Norwalk/Wilton Red Cross Bldg., 43 North Ave., Norwalk CT 06851.*

PORT TOWNSEND, WA Jefferson County ARC will operate at the Port Townsend Wooden Boat Festival, between 1700 UTC and 2400 UTC, on the General bands for 15 and 20m, and

28440 on 10m. The event station, W7LD, will reciprocate with an event QSL card. Send QSL and SASE to *Oilly Gardner KA6OZZ, Box 65156, Port Ludlow WA 98365.* Contacts will be made with Marine Nets.

TULELAKE, CA The Keno ARC will operate Station WD6EAW at the Tulelake-Butte Valley Fair. Operation will be in the lower portion of the General bands from 1600Z-2400Z. For a special QSL card, send an SASE to *WD6EAW Special Event, P.O. Box 653, Keno OR 97627.*

SEPT 10-13

PUT-IN-BAY, OH Members of the Oliver Hazard Perry Expeditionary force will operate KB8BN to commemorate the 180th Anniversary of the "Battle of Lake Erie." Frequencies: 7.240, 14.240, 21.365, 28.365. For a certificate, send QSL and 9" x 12" SASE to *Commodore Jim Yoder KB8LDG, 11796 Shadybrook Dr. NW, Pickerington OH 43147-9122.*

HIGHLANDS, NJ The Ocean-Monmouth ARC (OMARC) will operate 1600Z Sept. 11-1600Z Sept. 12, to commemorate the Marconi Memorial Twin Lights Lighthouse Radio Site. CW - up 10 kHz from bottom of Novice subbands; 10.145, 14.045, 18.080 MHz; bottom of General 80-15; Novice 10m phone subbands. For a certificate, send 9" x 12" SASE (or U.S.) to *OMARC, P.O. Box 75, Bradley Beach NJ 07720.*

SEPT 12-30

OAK RIDGE, TN The Oak Ridge ARC will sponsor a second Special Event, on all bands, to commemorate the 50th Birthday of the City of Oak Ridge, the site of the original Manhattan Project. "We were born of War, are Living for Peace and

Growing through Science." A four color certificate is available. Please SASE to operators' home call.

SEPT 13-18

ATLANTIC CITY, NJ Southern Counties ARA (SCARA) will operate K2BR for 5 days, from the Miss America Pageant (Absecon Island, IOTA: NA 111). Time: Starting at 10 AM EST. Frequencies: Phone - 25 kHz inside lower General bandedge; CW - 65 kHz inside lower General bandedge; Novice - 28.100, 28.500 kHz. To QSL, send #10 SASE via *SCARA, P.O. Box 121, Linwood NJ 08221.*

SEPT 18-26

KELLEYS ISLAND, OH Members of the Massillon and Canton ARCs will help commemorate the Lake Erie Commission Coastweeks projects by operating WD8DEA/N8LCS from the Kelleys Island Scuba Shipwreck tour Sept. 19th, and the Put-in-Bay Harbor Cleanup Dive, Sept. 20th. Operations will be in the General and Novice bands with phone on 3.880, 7.280, 14.280, 21.280 and 28.380 MHz. CW - 3.685, 7.110, 21.110 and 28.100 MHz. Packet - 145.07; phone - 147.475 MHz. Send QSL and SASE c/o *Jack Wade, P.O. Box 537, Kelleys Island OH 43438.*

SEPT 24-26

PEA PATCH ISLAND, DE The Tir-Cunly Amateur Group will operate KD3XN 1400Z-2100Z, from historic Civil War Fort Delaware. Operations will be in the General and Novice portions of 10, 12, 15, 17, 20 and 40m. For a color aerial view QSL, send QSL and SASE to operator worked.

SEPT 25-26

ECKLEY, PA The Down River ARC will operate N3JPS Sept. 25 1400Z-1800Z Sept. 26, to commemorate the 50th Anniversary of the original flag raising at Eckley Miners' Village in Luzerne County PA. Operation will be in the General subbands and in the Novice 10m subband. For a beautiful certificate, send QSL and a 9" x 12" SASE to *Rob Barnshaw N3JPS, 540 Church St., Royersford PA 19468.*

WARRENS, WI The Monroe County ARC will operate KA9ETH, 1400Z-2200Z Sept. 25; 1400Z-1900Z Sept. 26, to commemorate the 21st Annual Warren's Cranberry Festival. Frequencies: 14.270, 21.370, 28.370. For a certificate, send a QSL and a 9" x 12" SASE to *Marshall Kiel N9FVU, P.O. Box 344, Tomah WI 54660.*

OCT 2

ANAMOSA, IA The Jones County ARC will operate N0CWP 1500Z-2000Z, to celebrate their annual Pumpkinfest. Operation will be on the lower 50 kHz of the General subbands. For a certificate, send confirming QSL to *Jim McClintok N0CWP, Box 462, Morley IA 52312.*

OCT 2-3

BETHEL PARK, PA The Breeseshooters ARC will operate W3XX from the U.S.S. Requin SS481, a Trench Class WWII submarine, 1400Z-2100Z both days. Frequencies: Phone - 28.450, 21.350, 14.250, 7.250, and 146.52; CW - 28.150, 21.050, 14.050 and 7.050. For a QSL card and certificate, send 8 1/2" x 11" SASE to *Ron Berry WB3LHD, 326 Sunset Dr., Bethel Park PA 15102.*

Come to the 1993

AMSAT Space Symposium

La Quinta Inn & Conference Center
Arlington, Texas

October 8, 9 & 10

Your BEST chance to learn how to work

Amateur Satellites:

The high orbit DX satellites:

OSCARs 10 & 12

The "Easy birds":

RS 10 & 12

Store & forward PACKET spacecraft

AO 16, LU 19, UO 22, KO 23

and more coming SOON!

Now building:

Phase 3D (The satellite for ALL amateurs)

SEDSAT (Easy to use 2 to 10 meter transponder + digital)

PANSAT (An experiment in amateur spread spectrum)

RS 15 (A new Russian 2 to 10 meter satellite)

More PACKET satellites

Marjorie Swain with Grand Prize won at 1992 Symposium - a Kenwood TR-751A all-mode 2 meter transceiver. OM Carroll W7DU seems pleased with her good fortune.

NEVER SAY DIE

Continued from page 4

We're still the only group of communicators capable of providing dependable emergency communications. We're the only group able to help CBers, police, fire, and other fixed and mobile radio services communicate with each other.

But Not for Long

It isn't going to be long before we're going to see satellite communications making it possible for anyone to communicate with any car, truck, plane, boat or ship anywhere from Hawaii to England. I don't know how many outfits you have in your part of the country working on this technology, but we've got one in Manchester, New Hampshire, that's well along with a spread spectrum system which will let almost any number of units keep in touch. Companies will know exactly where every one of their trucks is at any moment, and will get instant word via a bar-code reader of every pickup and delivery. Your portable computers will be able to communicate with anyone anywhere via this network. Mobile units will not only provide positioning information, but will allow voice, fax, and computer communications . . . if you want.

The antennas for these little buggers are small enough to be built into car tops. And will be. Small umbrella-like antennas will allow HTs and notebook computers to join the network.

All this will probably take 10 to 20 years to become ubiquitous, but when it does why will anyone need amateur radio emergency communications? For what? Then what will be our excuse for keeping our bands?

Yes, of course I have a solution, but old-timers are going to hate it. Of course, with the average ham age in the 50s now, most of the old-timers will have been awarded their Silent Key certificates, so it's not their problem. My proposal is to get busy starting radio clubs in our schools and bring in a flood of youngsters. If we can turn amateur radio into a recruiting ground for high-tech interested youngsters we'll be worth our frequencies.

If you have the idea that the no-code license has attracted a big bunch of kids to the hobby, you are dreaming. The figures I've seen show that about 12% of our newcomers are youngsters. Back before we killed off 95% of the school radio clubs 30 years ago, 80% of all new licensees were youngsters. And 80% of them went on to high-tech careers.

If we can start attracting youngsters again we'll not only get them interested in high-tech careers, we'll start seeing some inventing and pioneering again. All of the major technical developments amateur radio has pioneered were made by relative youngsters. I know because I was there for many of them and knew the chaps involved personally. I was one of the first experimenters with narrowband FM (NBFM). Ditto

SSB. Ditto RTTY. Ditto SSTV. Ditto 10 GHz. Ditto 6m. Ditto beacons. Ditto repeaters.

No, I haven't done much lately. I got all wrapped up with computers almost 20 years ago and got sidetracked. Heck, I'm still wrapped up with computers. Then I got re-involved with hi-fi audio and digital sound. So now I have one of the finest recording studios in the world.

More and more of our ham clubs are sponsoring school radio clubs. Way to go. I'd like to see more pictures I can publish. And I'd like to see more about this in the club newsletters.

It's probably getting almost time to start discussing what we think is the best kind of license exam to go with hamming in the '90s. Our exams are still hung up back in the Dark Ages. What should a youngster be able to demonstrate to us to be worthy of a license? And does the long ladder of license classes fit in with hamming the way is today?

For many years I've recommended we change to just one class of license and depend on the fun of learning and doing things to build knowledge. The current licensing system is a joke. The test questions and answers are published, so it's purely a memorization exercise and has little to do with actually learning anything. It would be nice if our ham clubs would organize technical sessions at the start of their meetings. This might help the members to understand how antennas and feedlines work. It could help them understand the basics of receivers and transmitters. And how about some tech talks on packet, RTTY, SSTV, and other ham communications modes? Is your club offering tech sessions like these? Why not? This is supposed to be a technical hobby, right?

One of my problems is that I not only recognize that change is inevitable, I actually welcome it. I enjoy change. This may have a lot to do with the host of enemies I've generated . . . and every one of which I am proud. So let's think in terms of how things are going to change and how we can best adapt to it so we'll continue to have a hobby, even under the new conditions.

2020 Vision

What will amateur radio be like in the year 2020? Or will our hobby still be around? If so, what purpose will it serve that would validate its cost to the public? And what technological developments do we see emerging which will affect our future?

One fast-emerging technology which is encroaching on our turf is the network bulletin-board systems such as CompuServe and Prodigy. These allow people to go on-line and talk with each other about any mutual self-interest. An ad in *New York* magazine for their network has an international chat line where you can talk with people all over the world one-on-one in real time about anything you want. It also allows you to get information about restaurants, movies, plays, stocks, etc., and even play chess.

There are thousands of bulletin boards. Most are dedicated to special interests, but there are a growing number of wide-interest systems and people are getting caught up in these by the hundreds of thousands. Sure, they run up telephone bills, but there's no interference, no fading out, no pile-ups . . . just solid contacts.

Well, okay, on-line services are going to do nothing but grow. We're going to need help in finding out which services provide what, how good they are, and how much they cost to use. That information will be available on-line too.

But what about when we're driving or walking? Well, driving, since we don't walk much any more except to walk or jog just for the exercise it provides. We don't want to be out of touch just because we're mobile. Our systems will have to enable us to stay in contact when we're in our cars, on planes, or at sea.

It isn't going to take 27 years for satellite communications technology to extend our telephone wires, figuratively speaking, into our cars. By 2020 our homes and offices may all be connected by fiber optic networks. Or we may have gone all satellite. I expect it'll be a combo, with satellite links used mainly to interconnect to mobile units and fiber optics for fixed.

The amount of data we'll be zipping around will be far beyond what wires or even cables can handle. TV looks as if it'll be moving from 100 channels to TV-on-demand, making it so you won't have to record the 2020 version of "Murphy Brown" so you can see the program when you prefer instead of when the TV network program director decides. Your TV set will be more like tapping into a humongous video rental store. You may not even have to pay for the programs if you'll put up with the automatically inserted commercials. Fast-forward through 'em and your bill goes up.

We're already starting to see the development of spread spectrum satellite communications systems which will enable every car, truck, plane, boat and ship to tie into the network. People in cars will be able to keep in touch with anyone anywhere, either by voice, voice-messaging, or a fax-like system. You'll be able to be reached, but only if you want, no matter where you are. We'll adapt to this.

Since most of my work requires privacy, I'm reachable by phone about an hour a day. I read a lot. I write a lot. Neither of these activities are compatible with answering the phone or dealing with visitors. When I write I build a general picture of what I want to cover and then start getting it into my laptop computer. If someone comes in with a question or the phone rings, pffft, the picture is gone. So I do 99% of my productive work in my office at home. I drive to my business office for an hour or two a day for meetings with the staffers, and to answer phone calls. I use the 10-minute drive to review new compact disc releases, so even my driving time is productive.

I'm in touch with the office by phone and fax, if they need me. But I try to get my people to be self-reliant. I look for people who don't need much direction. It has not been easy finding them. Our school system, as I've written, goes to lengths to stamp out the very traits I find valuable.

I've gone into some detail on this because I believe more and more people will be wanting to work as I do. The day of the home-office is coming fast. As our communications systems improve there will be less need for going to "the office." We'll be able to video conference from anywhere for meetings. People wanting to talk with me will be able to find out what times are best (1000-1100 Eastern), and get through with one call. Even my production crew will be able to put together magazine pages remotely. From anywhere.

So where does amateur radio fit in when anyone will be able to talk with anyone anywhere in the world at will . . . and at a reasonable cost? When we have work on-line services where people interested in Italian Greyhounds can easily find and talk with each other, complete with video? When Gilbert & Sullivan fans can sing in groups, even when one is on a boat in California and another is driving in Maine?

We may even find people going to weird places to cater to a 2020 version of DXCC for people who are collecting the places they've talked with. Will there be pile-ups for some idiot fighting the tide on Minerva Reef? Computerized systems will allow tens of thousands of contacts per minute, so maybe not.

We do know one thing for sure. The communications systems of 2020 are going to require quite a bit of spectrum, even with spread spectrum systems, so we'll be losing our microwave channels before long. We've never used 'em anyway, so it won't seem like a big loss . . . at the time. They were a hold-over from the early experimental radio days that we will only appreciate after they're gone.

A few of us old-timers can still remember the stink when we lost the 7,300-8,000 kHz band and there was talk of the League having sold us out. The sudden building of expensive houses by several League officials didn't tend to quiet the rumors of a payoff for the loss of frequencies.

With the need for short-wave commercial communications eliminated by satellite and fiber optic systems, we may be able to not just hold on to our low bands . . . we may be able to increase them. Thus, in 2020, we may well see a few old-timers sitting there sending CW with their hand keys, just like they are now . . . and their grandfathers were 70 years ago. But the mainstream of communications will have passed us by. As commercial short-wave communications systems and broadcasting disappear we may be able to go back to spark on 200 meters, thus keeping alive the raison d'être of the American Radio Relay League. You can bet I'll be sporting my

80-year membership pin at Dayton in 2020 and showing holographic videos of my narrowband quenched spark rig.

"Nothing Endures Like Change"

The ancient Greek philosopher who said that wasn't speaking for amateur radio, where change is glacial, and fought bitterly. As Canadian Department of Communications official Peter Alien recently said, "Slow growth and a closed-shop mentality have led to the graying of amateur radio."

When I started hamming the entry code speed was 13 wpm and the technical exams were at about college level. In the late 1920s hams had to build their own receivers, since little was available commercially. As soon as commercial receivers were introduced amateurs stopped building them.

By 1938, when I talked with virtually every active ham in Brooklyn (NY), I was able to find only one ham who'd built his own receiver. We were still building our transmitters, not because building was fun, but because there were none available commercially. Not even kits.

After WWII we got busy converting military surplus transmitters, but it wasn't long before a wide range of commercial transmitters and kits appeared. That quickly put an end to around 90% of ham home construction. Pioneering hams still had to build VHF gear and gadgets for new modes such as NBFM, RTTY and SSB. But as soon as there were enough hams interested in a new mode, commercial gear became available and home construction blew away.

I built my first SSB rig in 1954. By 1959 Hallicrafters had a miniature transistorized sideband transceiver on the market which was far beyond anything I could hope to build. I made an around-the-world DXpedition in a MATS C-54 plane in 1959, operating SSB from 22 countries using Hallicrafters SSB equipment.

Old-timers can tell you about the bitter fights between AMers and SSBers in those days, as older amateurs fought change . . . and lost.

DOC's Alien laid it out on the line, and not only for Canadians: "How do we keep amateur radio from becoming extinct? Very simply, you've got to get out there and recruit new interest. Do everything you can to interest young people in ham radio. Advertise. Talk to people. Provide instruction and make it convenient for busy people. Could you convince your local high school to establish an after-school radio club, where a station can be set up? Could you convince school authorities to let you make 'Introduction to Radio Theory' a part of an electronics course?"

Amateurs today buy their equipment and get their enjoyment from using it. Perhaps our entry exams should reflect this reality.

When the first microprocessors became available, hobbyists built their own computers. Then, when commercial microcomputers arrived, hobbyists got busy building accessory boards for them. Soon there were enough users

so just about any board you could imagine was available, so hobbyists turned to software development and hacking. These days computer hobbyists can't hope to compete with mass manufacturing economies or with the humongous commercial software programs, so they're busy playing ever more involved computer games and calling in on computer networks and bulletin boards. There are now over 46,000 bulletin boards in the US.

In amateur radio, though we enjoy reading about building, only a tiny percentage of hams are actually building. There no longer are parts stores in every city. Or in *any* city . . . at least in America. There are some great kits available, but even this activity has dwindled. Maybe you noticed that Heath finally had to give up trying to sell kits, marking the end of an era. And Eico is long gone.

Alas, our license exams still reflect the thinking of a long-gone era. Morse code, which is no longer used commercially in the real world, is still being used as a barrier to keep as many people out of our hobby as possible. Our technical exams are woefully out of step with the reality of amateur radio today. But then even the whole basis and purpose (97.1) for the hobby is out of date, as I've mentioned recently.

No, I don't know how to get the message through to the closed-minded old-timers who are killing our hobby. I hear them at our ham clubs angrily fighting change. I see them epitomized in the good old boys' club in Newington. Let's get some young ARRL directors, for heaven's sake! That doddering old bunch you've elected, still grasping their hand keys to their chests, are leaving deep heel marks in the sands of time as they fight change to the bitter end.

So here we are, fighting over the deck chairs, as our ship, which has collided with the iceberg of change, slowly sinks. Rout the old-timers from your club. If they have tight control, bring in enough newcomers to oust them. You have to be prepared for a fight because the old guard will try to throw you out.

There's an egregious example of this with the Algonquin Amateur Radio Club in Marlboro, Mass. I've written to the president of the club (K1ZFJH) about his outrageous conduct, asking for an explanation. I got a brief note from him saying to contact his lawyer. Further correspondence from me has been ignored. My own feeling, often expressed, is that lawyers are brought into amateur radio matters only by scam. When the homosexual ham group sued QST, demanding their ad soliciting members be run, their strident leader went on my suer scam list.

We can't bring back the days of home construction. We can't bring back CW, other than as a small fun part of amateur radio . . . something some of us do because we enjoy it. We can't bring back AM. My workbench, with shelves of test equipment and a barn full of parts, is a memory. I enjoyed building my first narrowband FM

modulator and installing it in my Meissner Signal Shifter. I enjoyed converting a BC-459 to 20m and adding an NBFM modulator. I loved building my pp813 kilowatt final. I got a whale of a kick out of building my RTTY converter, complete with a dozen or so 6SN7GTxs. But those things are memories and when I'm gone, they'll go with me. Those memories are no reason to try and force today's prospective hams to build their rigs. Or to learn the code.

The SCR-522s which helped stabilize 2m are all gone now. Even my big box of crystals for the rig is gone . . . sold off in an auction almost 30 years ago. But I still remember every detail of that wonderful old rig. And I'll never forget the thrill of making 2m contacts from the top of the New York News building in 1948; the top of the Municipal building in 1949; and the top floor of the Guggenheim museum building in 1951. Or the wonderful RTTY net we had on 2m at that time. Sure, I had to build my own equipment in those days. But as soon as the stuff was available commercially I stopped building, right along with everyone else.

So let's give some thought to where amateur radio is going. Let's talk about what services we can render. Let's stop worshipping the past and trying to preserve it in our rules and tests. If we can't pay back society in some way for the use of our frequencies in the 21st century, we're goners . . . and those old-timers who were fighting you are going to be little more than forgotten Silent Keys listed in the yellowed pages of old QSTs up there in the attic.

Sure, I've had fantastic times in amateur radio. Times I'll never forget. I feel sorry for hams who haven't taken the trouble to do ham things. For hams who've never been on a foxhunt. Who've never won a contest for their section. Who've never made any satellite contacts. Who've never made any aurora contacts. Who've never worked DX on 6m. Who've never mountain-topped on VHF.

I remember sitting in the back seat of my old 1940 Ford on top of Mt. Greylock in Northwestern Massachusetts with my old SCR-522 and a 14-1/2 element beam, making contacts all over New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, and Long Island with three college buddies back in 1947. We'd driven up there one very cold night after a ham club meeting and we had a ball. We swung the beam from inside the car with some string tied to the ends. The beam, tied to the top of my car, had lost 1-1/2 elements on the trip over.

These days all it takes is a tiny HT and I can make contacts through a hundred or so repeaters from any good mountaintop. That was exciting back in 1969, when there were only a few repeaters. I had an old Motorola HT-220 and was able work all over New England with it. My mobile 2m rig got me down to Maryland repeaters when we'd have morning temperature inversions. I hope you're building a lifetime of ham memories.

Oh, my first DXpedition! Wow! That was in 1958 and six of us went to Navassa. I'd gotten KC4AF for our call. I think I may be the only one left out of that group. The others died off or disappeared. I still have some great 16mm film of the DXpedition. But most important are my memories of every minute of the experience. The hurricane during our trip down where we almost ran onto a reef. The time we were almost killed by Haitian police. The pile-ups! The glorious, endless pile-ups. Running out of water. My having to dive in the shark-infested waters to retrieve the beam elements we'd dropped. The heat. The dangerous cliff we had to climb to get to that uninhabited island with no beaches.

My contact with Moscow via OSCAR VII, where we had only a 20-second window to make the QSO.

My wonderful visit to New Caledonia, where I worked the pile-ups for a week and got fabulous pictures of the island from a local ham's plane. And my aerial photos of VK3ATN in Birchip, Australia, and his 2m moonbounce antenna. I used to fly, but I had to sell my plane when I started 73. And my boat, too. And my Arabian horse, and my Porsche. All that went into printing the first issue of 73 back in 1960. Fortunately, the magazine was in the black from the first issue . . . or else it wouldn't be here now. That's the way entrepreneurs are, they gamble everything on a new business.

Many times since then I've not known whether I'd be in business another month or not, but I've always managed to make it.

I remember the first time I worked all continents within one hour. And the weekend I worked 100 countries on 20m phone. And the night I worked all states on 75m AM. Other events may fade from my memory, but my ham experiences stand out clearly, even years later. My nights making contacts with King Hussein in his summer palace. My dinner with him, his wife and in-laws. Working SSTV from Navassa on my second trip in 1973 as KC4DX. Working SSTV from Jordan as JY8AA, and from JY1's station in his downtown palace. Setting up the JY73 repeater in Amman. Working my home station from YK1AA in Damascus, and then again from VK3ATN, where we shifted from 20m to 75m and my W2NSD/1 signal was still S9. The wooden "matress" and cold showers while staying with Father Moran 9M1MM in Katmandu. The friendliness of hams in well over a hundred countries I've managed to visit so far.

My advice to youngsters is to build your ham memories. Do everything you can in the hobby. Amateur radio holds enormous adventure for you if you'll just grab the ring as the merry-go-round turns. My 10 GHz contact with New York State from the top of Mt. Monadnock (NH), where I'd struggled to the top with a three-foot dish, just in case. The top of the mountain was in dense fog, so I had to aim the dish with a compass. Even though my tenth watt signal had to go over a mountain to

make the path, we made a good solid contact. There's no way I'll ever forget that moment. That was my seventh state on the band!

Work DX. Get good at contests. Collect certificates. Get on OSCAR. Do packet, RTTY, and SSTV. Do it all. You'll never regret a minute of it. Looking back on 56 years of hamming, I don't. Perhaps this is why I'm so strident about our coming to grips with change. Why I feel that we need to keep amateur radio in step with the times and not try to keep it a monument to a long-gone past.

Why Democracy has Failed

Yes, I know, if I say white, you automatically say black, so you're going to try and say that democracy has not failed in America. And I say "baloney." I shouldn't have to remind you that the foundation of democracy is an informed electorate. Well, I hope you're not going to try and convince me that a country where less than half the people are interested enough to vote, and most of those who do vote on the basis of sound bites and political commercials on TV, is what our floundering forefathers had in mind when they set up this mess?

They thought they'd set up a citizen's legislature, not a new class of professional politicians whose dominat-

ing goal in life is to get as much money as possible from special interests so they can be endlessly re-elected.

The sorry fact is that there are so many complex problems today that it is completely impractical for the average person to find out what's actually going on. When I signed on as a member of the New Hampshire Economic Development Commission almost two years ago I knew I had a lot of work to do. Well, I dropped just about everything else and went to work. I read every book I could find on education, welfare, taxes, business growth, the international situation, creating jobs, health care, racial problems, crime, our prison system, stopping drugs, and so on. I attended endless committee meetings, have heard testimony from experts on a wide range of problems, and have attended a ton of conferences on exporting, defense conversion, job creation and so on.

Few people have the time and patience to do that kind of research. Yet, without it, how can any of us make informed decisions when it's voting time? How can we write to our representatives to give them our guidance if we don't know what we're talking about? We hear half and quarter truths from most of our politicians. We're at the mercy of political action committees and lobbyists with millions of dollars to

invest in bribing Congress and our state legislatures. It's been well documented that we're getting left-wing bias from our media. So we sit here watching one exposé after another of corruption in savings and loans, banking, housing, defense contracts, health care ripoffs, government land scandals, farm and tobacco subsidies, and endless Congressional pork projects.

To listen to the liberals in Congress, there's no way to cut back on "entitlements." Yet, if they don't, the deficit is going to keep right on growing. Then there's the conservatives who want to set up a virtual dictatorship and control our every move. Phooey.

I Have a Solution!

Yes, I believe democracy is still possible! The electorate can still be informed, and without having to spend two lousy years trying to understand what the hell is going on with the endless messes Washington has created. Well, we're the guilty ones. We're the dummies who elected those crooks. We've let those bozos bamboozle us with emotional TV spots into giving them our checkbooks with all the checks pre-signed. We even elected Charmin' Billy from Arkansas.

So what's the out? Well, one way is to let fools like me do most of the work, digesting the mountains of conflicting

trivia and giving you the results in brief readable form. A digest. And that's what I've been doing with my reports, which are sent to the New Hampshire Economic Development Commission, the Governor, and the Legislature. Each one is 16 digest-size pages long. Reading time is about 15 minutes. I'll be putting 'em on tape for people to listen to in their cars. Each report takes about 20 minutes to read out loud. I put 'em out twice a month.

You can let me do the homework . . . read the books, attend conferences and hearings . . . and tell you (a) what I've found out and (b) offer some creative solutions to the major problems facing us all.

All this can be yours for only \$20 for 20 issues. A steal. Send me a \$20 bill, a check, or your credit card information and I'll get you a bunch of my *Updates*. They'll give you plenty to talk about on the air, that's for sure. And, if you're even remotely inclined to make money, there's a wealth of entrepreneurial ideas in 'em. Send your \$20 to *Updates*, WGI, Peterborough NH 03458-1107. Or fax your credit card info to 603-924-8613.

You'll be able to drive your family and friends crazy by knowing more about just about everything than they do . . . and by coming up with brilliant solutions to the problems. 73

2-1000 MHz In One Sweep!

AVCOM's New PSA-65A Portable Spectrum Analyzer

The newest in the line of rugged spectrum analyzers from AVCOM offers amazing performance for only \$2,855.

AVCOM's new PSA-65A is the first low cost general purpose portable spectrum analyzer that's loaded with features. It's small, accurate, battery operated, has a wide frequency coverage - a must for every technician's bench. Great for field use too.

The PSA-65A covers frequencies thru 1000 MHz in one sweep with a sensitivity greater than -90 dBm at narrow spans. The PSA-65A is ideally suited for 2-way radio, cellular, cable, LAN, surveillance, educational, production and R&D work. Options include frequency extenders to enable the PSA-65A to be used at SATCOM and higher frequencies, audio demod for monitoring, log periodic antennas, carrying case (AVSAC), and more.

For more information, write, FAX or phone.

NEMAL ELECTRONICS INTERNATIONAL

Nemal Electronics International has introduced a new line of composite RF/control cables for use in two-way communications, and especially for amateur radio applications. The "HAM-CABLE" is constructed of a coaxial cable and an eight-conductor rotor cable with an overlay weather-resistant jacket. Available versions include RG8, RG8X, and RG213 for coaxial members with either standard 8C1822 or heavy-duty 8C1620 for rotor control. Part number HC100 consists of RG8 low-loss foam, together with 8C1822 and a black jacket. Other constructions and other colors are available by special order. For additional information, please contact *Nemal Electronics International, Inc.*, 12240 N.E. 14th Ave., North Miami FL 33161; (305) 899-0900, Fax: (305) 895-8178. Or circle Reader Service No. 203.

MIDLAND LAND MOBILE RADIO

Digital hams will be interested in this new, built-in two-way radio modem. Midland LMR has introduced an internal modem for its Syn-Tech XTR two-way mobile radios and desktop base stations that provides a built-in data interface. With the internal modem a wide variety of data sources, such as GPS receivers and other vehicle location systems, vehicle sensors, mobile data terminals and PCs, can be plugged directly into the radio.

This integrated radio/modem design optimizes data communications performance and reliability, simplifies installation and saves space; no extra boxes are needed. The modem is capable of data rates up to 9600 BPS, with forward error correction, and supports RS-232 or TTL interfaces. For more information, contact *Midland LMR*,

Marketing Department, 1690 N. Topping, Kansas City MO 64120, or call 1-800/MIDLAND, Ext. 1690. Or circle Reader Service No. 204.

ELECTRON PROCESSING

Hams needing a simple repeater interface that is easy to install and operate can now select a special ruggedized version from *Electron Processing, Inc.* This unit is right for use where either the RF or mechanical environment demand more than a standard enclosure.

The new BRI-2-ALB is housed in a strong cast-aluminum box that is only 2.5" x 4.5" x 1" in size. This new model contains all the features of EP's BRI-2, including a super-sensitive VOX, and both hang and timeout timers. In addition, a rugged transmitter keying relay is included which will handle up to 10

amperes of keying current at 230 VAC or 30 VDC! A passive audio matching circuit assures clean transmitted audio.

The BRI-2-ALB is priced at \$70, plus \$5 S & H. For further information, contact *Electron Processing, Inc.*, P.O. Box 68, Cedar MI 49621; (616) 228-7020. Or circle Reader Service No. 206.

THE TOOL RESOURCE

The Tool Resource has introduced a new No-Clean Wire Solder. The Alpha Telecore Plus No-Clean Wire Solder was developed to meet the highest demands that exist in electronic hand soldering. It leaves only a miniscule amount of optically clear inert flux residue. The development of this product is a result of the shift away from ozone-depleting chemicals that are used in electronics for batch or spot cleaning.

Telecore is a core solder that contains a Water White gum rosin base with an efficient activator system that promotes rapid solder wetting of board pads, component leads and terminations. Although this solder is designed not to need cleaning, it can be cleaned if necessary. For more information

contact *The Tool Resource, P.O. Box 1106, W. Dundee IL 60118*, telephone and Fax: (708) 468-0849. Or circle Reader Service No. 202.

ZERO SURGE

Here is a new patented surge protector that never contaminates ground. The Model ZS1800 surge protector from Zero Surge provides fast suppression of power-line surges to protect microprocessor-based computers, networks, and peripherals. Rated at 15 amps, it eliminates spikes and surges without relying on commonly used MOVs (metal oxide varistors). As a result, this surge protector not only eliminates surges on the 120 volt hot wire but also keeps the power-line ground circuit clean, eliminating diverted surges which MOVs routinely dump onto the ground line.

Experts report that ground-line surges, especially in UNIX and network installations, can cause many

mysterious problems, such as blown peripherals, keyboard lock-up, and lost or corrupted files. Zero Surge products never dump surges to ground, thus eliminating most of these problems before they can ever occur.

Unlike most other products, the ZS1800 reacts to surges and spikes instantly, diverting the surge to a capacitor bank which stores the unwanted energy. The unit gradually bleeds it back to neutral without damaging surge-energy pulses.

The suggested retail price is \$199.95, and this product carries a 10-year warranty. For more information contact *Zero Surge, Inc.*, 215 Glenridge Ave., Montclair NJ 07042; (201) 744-1760, Fax: (201) 744-1804. Or circle Reader Service No. 205.

HARLAN TECHNOLOGIES

Now, a new inexpensive method of copying slow-scan TV from Harlan Technologies uses software and a Sound Blaster compatible sound card with a PC. Slow Scan II will work with the Sound Blaster, Sound Blaster Pro, SB16, Pro Audio Spectrum 16, Fusion

16, and other Sound Blaster compatible sound cards. The program will copy Robot 8, 12, 24, and 36 second black and white, Robot 36 and 72 second color, and Scotty versions 1 and 2. All color modes display in black and white.

Slow Scan II will also re-transmit pictures that were received and can save them either as .VOC files or in the .PCX format. System requirements include a PC with a hard drive, a VGA monitor capable of 640 X 480 / 256 colors, and a Sound Blaster compatible card.

The price is \$40 plus \$5 S & H. (Illinois residents add \$2.50 tax.) For more information or to order contact *Harlan Technologies*, 5931 Alma Dr., Rockford IL 61108; (815) 398-2683. Or circle Reader Service No. 201.

Contract: Congratulations! You have just been drafted by Uncle Wayne and the Team. Your first assignment is to contribute a clear, concise, and complete manuscript for publication. Drop us a line and we'll gladly send you a "How to Write for 73" package. Now get out there and enjoy your hobby. Dismissed.

NEVER SAY DIE

Wayne Green W2NSD/1

Have You Seen *Radio Fun* Yet?

Well, I know the answer. No, you haven't. Because if you had you'd be a subscriber.

I started *Radio Fun* as a way to help the new no-coders get more fun out of amateur radio, and to encourage them to go for their General and Advanced tickets. I wanted them to find out how much fun we're having with packet, slow-scan, fast-scan, our ham satellites, radio clubs, DXing, certificate hunting, building kits, foxhunting, RTTY, emergency nets, and so on. I wanted them to know that amateur radio has a lot more to it than listening to old retired men talk about their illnesses over the local repeaters. Or, as in the case of our Ham-O'-The-Year award winner at Dayton this year, driving everyone within repeater range nuts extolling my virtues and my Horatio Alger success story.

So, how's *Fun* doing? Pretty well.

We've been sending it to every new licensee for about five or six months for free. Why for free? Well, I noticed that *QST* was having surprisingly little luck in getting new hams to subscribe. My idea was to get them really involved in their new hobby while it was new and they were still excited about it. But how many readers could we convert to paying subscribers? That was the key question. You can't give things away free forever.

Thirty years ago, before our mail boxes were as stuffed with junk mail, it was possible to send out a subscription offer for a magazine and get 10-12% of the people to subscribe. These days a 2% response is considered outstanding, with 1% being in the "good" range in the business. With today's postage rates we have to figure at least 60¢ per letter sent out. That's \$600 per thousand. At \$13 for a year's subscription and a 2% response we'd get 20 subscribers and \$260 back for every \$600 we spent. We didn't go that route.

Instead, I decided to let the publication do the selling instead of letters. It costs around \$5 to send five issues, so the question was, what percentage of the readers would pay to subscribe after getting the five issues? That's about the same cost as sending eight letters. And eight letters might, at best, bring in a 16% response. So, have we been doing better than a 16% sale with the free sample route? You bet

we have!

Out of 1,027 expired free subs in January, only three didn't renew! That's right, we got a 99.7% renewal! Nothing like that has ever happened in the publishing business before, so I expect we'll be getting excited write-ups in the publishing magazines. We should check and find out why the three didn't renew. Did they lose interest in amateur radio? Maybe they died?

Radio Fun obviously is terribly addictive. You tried it yet? The subscription price is a ridiculously low \$12.97, though if it gets much thicker we'll have to raise it just to cover the postage. You can give it a try by sending a check for \$12.97, or credit card info, for 12 issues to *Radio Fun*, 70 Route 202 N, Peterborough NH 03458-1107. You can even call 800-257-2346 or fax us at 603-924-9327.

The *Fun* advertisers are delighted. It turns out that my research was right . . . that our newcomers are the biggest spenders in the hobby by a wide margin. They're buying tons of VHF rigs, low-band transceivers, HTs, packet TNCs, antennas, and so on. Wow, are they buying antennas! Indeed, without this new bunch of big spenders, the ham industry would be suffering far more seriously from the recession. Fortunately for our *Fun* advertisers, much of the industry is still stuck advertising in *QST*, so the competition for this bonanza has been low.

\$12.97 may not buy much these days, but it'll get you 12 months of *Fun*.

A Bigger, Fatter 73?

If you'd like to see more pages of construction articles and equipment reviews in 73, that's easy. No, my editorials won't get longer; the additional pages will be used for more articles. Like back in the late 1970s and early 1980s.

How can we do that? The formula is simple: For every extra page of advertising we're able to sell you'll get an additional page of articles. So how can we attract more advertising? Your complaining to the advertisers might help a little, but probably not much. They advertise in the magazines claiming the highest circulation. So, if we have 65,000 paid readers and *QST* has 130,000, that's where most of the ads are going to go.

How come *QST* has double our circulation? And what, if anything, can be

done about it? Well, 73 was doing fine until I had to sell it 10 years ago.

I'd started a bunch of computer magazines back when the microcomputer industry was just getting started. Eventually the megapublishers with deep pockets came along and offered me a choice of selling my magazines to them or going out of business.

I got the best offer I could for my entire publishing company. That left me with no way to publish 73, so that went along with the computer magazines and I had to start all over again to build a new publishing business. It took a while before I had a big enough organization to be able to take back 73. By that time the computer publisher had come close to killing it. The circulation was down to half, and so was the advertising. There were an awful lot of disgusted ex-readers and angry ex-advertisers. And once you make customers mad they are incredibly difficult to ever get back, so we've been kind of limping along at half strength ever since.

I made a deal to publish 73 on contract, as a way to save it. I put my editorials back in and increased the construction projects and equipment reviews. Then, last year, I swapped *CD Review* for 73 and finally got back the ownership. Now I'd sure like to get it growing again and make it the biggest magazine in the ham field . . . the way it used to be.

If every subscriber would get just one other ham to subscribe, we'd really raise hell with *QST*. Once we have even close to their readership we'll get plenty of advertising and be fatter than they are. All it takes is circulation. Many advertisers aren't happy with *QST*, but it's got the largest circulation.

Subscriptions to 73 are \$20 a year, so if you can get at least one other ham to send us \$20 for a subscription, I'll have one whale of a magazine for you. One without all that baloney club news which fills so much of *QST*.

We are, by the way, the only ham magazine which has Audit Bureau of Circulation certified circulation numbers. The others we have to trust that they're not . . . er . . . being generous in their circulation estimates. But then, they wouldn't lie, would they? Not just to get more advertising dollars from gullible advertisers. It would never even occur to me to accuse my esteemed publishing colleagues of such villainous perfidy.

By the way, while it's a no-no for me to go on the air and solicit 73 subscriptions, there's nothing to prevent you from bringing up the subject when you run out of more important things to talk about . . . if there are any. It sure beats those old tired weather reports and cliché recitals of your equipment and antenna model numbers. If enough readers keep mentioning the magazine, it'll gradually begin to seep into even a few of the denser consciousnesses.

Your reward for all this? Firstly, I can assure you that you will be richly rewarded in heaven. I have connections. Secondly, you'll start having more magazine to read. A lot more. And the more stuff we have, the more fun you'll have reading it. We might even get your juices going and get you off dead center and into satellite communications or something.

That Lap of Luxury Deal

There's this myth about Wayne living in luxury on the enormous profits from 73. Har-de-har. Oh, I can't complain . . . but that's because other ventures have done well. Ask anyone who knows me and you'll find that NSD stands for never spend a dollar. I'm cheap. And whenever I do manage to end up with some money I quickly invest it in a new venture, thus getting rid of it.

I think I mentioned that Sherry and I spent a week in Rome in April this year. When you're rich you can travel, right? Well, it turns out that the more you can get your business to charge things on a Continental Airlines Master Card, the more free trips you can take. Our week in Rome, complete, cost \$551. Fine hotel, great meals, sight-seeing everything, the works. You don't have to be rich, just smart.

Sherry has had three extravagant things she's wanted us to do. Her how-to-dance videos have been doing well, so she's arranged for us to fly to London on the Concorde, spend a week, and come back on the QE2. Maybe next year we'll do the Orient Express.

We'll be leaving Dec. 9th, in case your wife has some extra money stashed away and you'd like to join us. We get back the 19th. There's a special combo price, so it's a way to get in two big events in one trip. Your wife won't forget it. Heck, neither will you. I did a Concorde trip 10 years ago and I still remember every minute of it. I'm still using the Concorde playing cards to play cribbage. And win. Nobody beats me at cribbage. Nobody.

If you're interested let me know and I'll have Sherry get you the details. It'll be even more fun if we've got some friends like you along.

Are You a Dreadful Bore?

I'm still getting endless letters complaining about how boring most ham contacts are. They're not talking about *you*, are they? When's the last time, when they were signing off, that someone told you how much fun they'd had talking with you? Will they give you a call the next time they hear you on the air? Do other chaps break in at the end of a contact to tell you they've been listening and enjoying it?

Continued on page 74

From the Hamshack

Keith Bruno KC4ZV, Orlando FL
Wayne—Your last issue of 73 inspired me to finally take some time out of my schedule and write. Let me first state that you have a fine magazine and it is the best amateur radio publication in existence, hands down. I have read them all, but have only kept up my subscription to yours.

I agree with almost all of your opinions, especially those relating to the farce called government. Most of your ideas for change are very logical. Unfortunately, that is precisely why the government will probably never listen to them.

You are always bashing the educational system of our "fine" country and I would like to further reinforce that opinion. I am a product of our poor educational system. I graduated from high school in 1983, nowhere near prepared for the real world. I can honestly state that I was bored with most of the subjects in high school, except for computer science. Luckily, I got a great job right after high school working for the world's largest defense contractor and had some great opportunities to pursue my first love, computers (my second being amateur radio).

I have to say, though, that if one wants an education, it is out there. Ninety-five percent of everything I have learned about computers, and ninety-nine percent of what I have learned about amateur radio I have learned on my own. Right now I am enrolled in the NRI course for Radio Electronics and hope to get my General Radio Telephone Operator's License. There is no one who is responsible for my education and my well-being except me. I hate it when people grumble about how they never had a chance, or that the world owes them a living. Baloney! Get out there and get yourself an education. Stop complaining about your life and do something about it.

My wife is always making fun of me. I am 27 years old now and always seem to get involved in what she calls "old men's hobbies." It is a shame, but at the club meetings I go to almost everyone is over 40, with most of the guys in their 50s. I may see one or two kids, but that's it.

And as for offering any help, forget it! No one, not even the local amateur radio shop, is even helpful. As a matter of fact, they all seem to have this attitude that if you don't already know, then they are not going to take the time to explain it. Pitiful!

I have taken your advice to try something new and have gotten into packet. Again, I had to dig through the manuals and call the manufacturer to figure out how to connect it to my computer and radio. I want to figure out how to link my two computers together with some software like PC Anywhere. I figure if they can do it over the phone, then I should be able to do it over the radio.

I have a no-code Technician license. I got it before they even had a formal no-code test, about two months after they came out with it. I do not plan to upgrade until the code requirement is dropped. I really have no desire to ex-

change call signs, QTH, and a signal report with some old guys who have never done anything but pound on those brass keys. Heck, if I need CW to "punch through" in bad conditions, I'll hook up my multimode controller and type on the keyboard and let it send CW.

Adam Halle NØVCL/AE, Sterling OH
Wayne—I am writing in response to your editorial in the May 1993 issue of 73. You were right about schools. I am 14 years old and I am home-schooled. We are wrapping up our second year. I have enjoyed homeschool very much. These two years have gone by faster than any two years in public school.

For science (up until April of this year), I studied radio and electronics theory. I began studying for my Technician Class license in October 1992. On April 6, 1993, I upgraded to Extra Class. While getting school credit, I did something I enjoyed doing. I could not have done this in public school. Now I have gotten my dad interested in ham radio and he is studying for his Technician license.

Also, I agree with your editorials on EMR. Keep up the good work. Your ideas are very good, and they get better as more research is done on this subject.

Bruce Williams N9JCV, Lake Villa IL
Six months ago I purchased an ICOM 728. I love it. I had a problem with it (the preamp went out). I sent it back to ICOM for warranty repair and it was back in my shack two weeks after I sent it away.

Yes, I bought a kit also. I purchased a Ramsey 30m transceiver, spent three hours putting it together, and it works like a charm.

I used to work all SSB, 100 watts. I got my WAS, WAC and DXCC (applied for). I am now very interested in QRP operation and building. By the way, 73 does a great job supporting QRP endeavors. I think everyone should cut their power by 50%. What nicer bands we would have.

Wayne, I don't agree with everything you write, but I always read your column from front to back as soon as I get 73.

Oh? What in hell don't you agree with? . . . Wayne

Bill Eaton N9OTZ, Elgin IL
Wayne, along with so many other hams, I enjoy 73. The deciding vote for 73 vs. CQ or any other publication is your editorials. It's so refreshing to hear intelligent, well-thought-out ideas and viewpoints. Of yet I've found no point of contention, although I suspect we may differ on religious ideas.

In January 1992, my partner (I'm a paramedic) was browsing through a handie-talkie sale pamphlet. "Neat looking scanner," I said. From that point on my understanding of ham radio as a bygone hobby of yesteryear, consisting of an oversized, tube-operated transceiver, a Morse code key and an antenna that made neighbors nervous, has changed. I was licensed in March and

have loved the hobby. I've met many hams, all of whom have confirmed my pastor's comment of ham radio as "a gentleman's hobby." From these meetings I've seen everything from 20 meter DX to ATV balloons and ATV with the shuttle spacecraft! Needless to say, this keeps my motivation alive to upgrade and expand. The only thing that holds me back is time and money (not necessarily in that order).

Frustrations? Yes. The pathetic lack of any substantial, in-depth conversation. On my attempts to initiate such, the normal response is, "Oh, that's interesting . . . Well, what kind of radio are you using?" or "How's the weather?" Once in a while it works, though.

Here's a new thought on the service/hobby issue: Any hobby that requires initiative and learning, that may lead one to higher education, etc.—keeps kids off the street!—is a service. It may lead someone to your editorials and get them thinking. Now, that's service!

Now for my pocket review: the Yaesu FT-415 2 meter handie-talkie. After a year and a half of almost daily operation, the only problem I've encountered so far is that the click stops on the frequency dial quit clicking and stopping. My dial began to turn freely, scooting up and down frequencies with annoying speed. Being an excited newcomer to the hobby, I bypassed factory service and fixed it by slipping a small plastic tube over the dial post and replacing the knob. This makes for a nice snug dial which still functions well. I've always received good reports on audio quality. A fine feature of most handie-talkies is that your hand gets burned if you talk too long, keeping a check on the motor-mouth syndrome.

Fixing things yourself? What are you, some kind of troublemaker? . . . Wayne

Richard Monjure, Covington LA
Wayne, I see comments about other hams in your column. There are all kinds of people in radio, and they talk about varied topics. Topics such as racial separatism, homosexuality, politics, etc., are offensive to some, but there is a bigger issue involved. That is "Freedom of Speech," which is in our Bill of Rights and in the Communications Act of 1934. So, as unpleasant as certain topics are, I would not shut up those who discuss them as long as they operate according to the radio regulations.

I make my living in radio. I know the limitations of CW, but it is still possible to send a telegram via CW, despite what some writers in ham radio magazines say. A large portion of the world's merchant ships still use CW. The reason many hams cannot accept this is that so very few hams really understand CW.

If you cannot copy 20 WPM you cannot expect to handle traffic efficiently on manual Morse circuits. The ability to receive code using a typewriter is also a requirement. You hear hams who say they copy "words, not letters." Come on! You cannot copy that way and expect to have the accuracy required for traffic handling.

The professional CW operator must have readable sending at a good speed. Automated keying is a must, unless you are good on the key. What do you hear on the ham bands? Operators who equate skill with speed. They send faster than they are able to legibly

transmit and wind up having to correct nine out of every 10 words they transmit.

What is the point of all this CW talk? The vast majority of hams cannot work CW due to lack of skill and understanding of that very mode. Extras Included. Any ham radio operator who wants to work CW should pass a real code test and have a CW endorsement on his license before he is allowed to operate on the CW bands. I believe CW is limited compared to modern data methods, but it has its place.

Which leads me to the question of no-code licenses. I do not feel code ability should be required for ham radio operators not operating CW. In my opinion, all the different license classes are not necessary.

An entry level amateur radio operator test should cover theory on the basics because everyone needs basic knowledge to build on. Past that, the test taken should depend on which mode of communication you plan on using.

Operators should understand the circuitry, bandwidths, etc. used in their mode of choice so they know how to use it properly on the air within the technical regulations set forth by the FCC. It is too bad the testing is not directly in the hands of the FCC anymore. I see no problem with a \$35 license examination/renewal fee.

I think it is terrible that anyone can buy books with the exact questions and answers to the amateur exams in them. That should be stopped. Whatever rule has to be changed should be changed to end this cheating.

I do not think the UHF frequencies are so important to ham radio. Some should be available to experimenters, but the ham radio role as a back-up communications system I think is a natural for the HF range. Most commercial communications, except for Maritime Mobile, have abandoned HF in favor of satellite communications. Hams could be a natural to fill this "void." The new digital modes make this feasible.

Richard—I'm not aware that I have suggested a limitation on discussion subjects on the air. I am opposed to the use of bad language, even though that is protected by the Constitution. It isn't necessary to offend people. As far as religion and politics are concerned, I like Glasgow's quote: "The fewer the facts, the stronger the opinion." I enjoy talking politics and religion on or off the air, as long as I'm talking with a thinking person and not a zealot.

Fine on CW. But why bother testing the code when someone using it has to be able to copy to do it? That's self-testing.

The microwave ham bands probably won't be a problem for long. Satellite bands are going to be in such enormous demand that we'll lose 'em all fairly soon. Too bad. It would be fun to have a ham satellite system which would allow an unlimited number of us to communicate anywhere in the world 24 hours a day. With spread spectrum, this is possible. There's an outfit here in NH developing just such a system. It'll make it possible for any car, truck, boat, ship, etc., to be in constant communication anywhere with any fixed or mobile stations with voice or data. I doubt there'll be much more of a need for ham emergency services once this gets going. It's a kind of super cellular telephone. Cheers . . . Wayne

FCC Relaxes Business Restrictions

The Federal Communications Commission has enacted a major change in the law restricting amateur radio use for personal business and public service. Under the new rules, it will no longer be a violation to order a pizza or make an appointment via amateur radio. The Commission has acted to amend the Part 97 Amateur Service rules allowing for more flexibility in personal business and public service communications.

The amendment permits licensees to use the amateur service frequencies to assist with public service communications at races, parades, and educational activities. Personal communications which will no longer be prohibited include making appointments, ordering food, and collecting data for the National Weather Service.

Effective 30 days after publishing in the Federal Register (approximately September 15th), here is what you can do (with some exceptions) on the ham bands:

Any amateur-to-amateur communications are now permitted unless:

- a. Specifically prohibited. These include:
 1. Music (except for incidental space shuttle music);
 2. Communications facilitating a criminal act;
 3. Messages obscured by codes or ciphers;
 4. Obscene or indecent words or language; and
 5. False or deceptive messages, signals, or identification.
- b. Transmissions for compensation. The following exceptions apply:
 1. Morse code practice and information bulletins (special criteria);
 2. Classroom teachers using ham radio in the classroom.
- c. Transmissions for the pecuniary benefit of the station control operator or his or her employer.

The following communications are permitted, but not on a "... regular basis" (not defined by the FCC):

1. Communications which could be reasonably furnished through other radio services;
2. Notices concerning sale or trade of amateur station apparatus; and
3. Retransmissions of government provided space shuttle, propagation, and weather forecast broadcasts.

Here are some examples of the old and new part 97.113 which covers prohibited communications:

OLD RULE: No amateur station shall transmit any communications which promotes the business or commercial affairs of any party. If anyone profits financially, it is an illegal transmission.

NEW RULE: An amateur may not be paid, direct or indirect, for his voluntarily provided

communications.

OLD RULE: Except for emergency communications, the ham bands may not be used as an alternative to other authorized radio services.

NEW RULE: Amateur-to-amateur communications which could reasonably be furnished alternatively through other radio services will now be permitted on the ham bands—although not on a regular basis. This will allow amateurs to legally participate with the Weather Service, police and fire departments, parks and forestry service, and many other local, state, and federal agencies. *TNX Westlink Report, No. 654, July 29, 1993, and W5YI Report, Issue 16, August 15, 1993.*

Technician is Hot Ticket

The Technician Class amateur radio license is maintaining its accelerated growth rate of 20%—by far the fastest growing ham class. Before 1991, amateur radio overall grew at only a sluggish 3% rate. Today, that figure is a healthy 10%. If the rate of growth of amateur radio continues on the track it's on now, we will surpass one million licensed ham operators by 1998.

In 1985, only one amateur in five was a Technician. But since the arrival of the Codeless Technician Class in 1991, the demographics have shifted significantly. Today, one third of all hams are Techs. *TNX W5YI Report, Issue 13, July 1, 1993.*

2 Meter Transmitter for AMSAT Phase 3D

The AMSAT Phase 3D Satellite will don a snappy new 2 meter transmitter, designed and built by Mike Dosett G6GEJ. This task will be undertaken as part of AMSAT-UK's participation on the international project team. Mike described his proposed design at the recent AMSAT-UK Colloquium held at the University of Surrey in England.

Together with the 70cm uplink receiver being constructed in Germany, the AMSAT-UK-supplied 2 meter transmitter forms a mode UV station, (also known as Mode B on OSCAR). Current users of Mode B on OSCARs 10 and 13 can look forward to better performance with the launch of the new bird, slated for April 1996.

Calling All Home-Brewers

The Radio Amateurs of Canada are making a call for papers for the Technical Symposium of their First National Convention. Papers concerning both the technical and practical aspects of ham radio are welcome. Subject areas include: HF, VHF, and UHF communication methods and techniques, packet, AMTOR, RTTY, AMSAT, and EME.

The papers will be featured in a 30-45

minute presentation and a 15-minute Q & A session with the audience. They will also be printed in the Technical Proceedings of the First National Convention of R.A.C.

R.A.C. Convention '94 will take place in Calgary, Alberta, Canada, July 29-31, 1994. For further information please contact: G.W. (Gerry) Shand VE6BLI, 55-51551 Range Road 212A, Sherwood Park, AB, T8B 1B2 Canada; (403) 922-2099, FAX (403) 438-4398.

Clinton is High on Hams in Space

The president of the United States, no less, took time out of his busy schedule recently to extol the virtues of the Shuttle Amateur Radio Experiment (SAREX) program. While talking to the STS-57 mission astronauts on a special hookup, President Bill Clinton said: "I understand that later in the mission Janice (Voss) and Brian (Duffy NSWQW) are going to be talking with schoolchildren around the world. I just want to tell you how much I appreciate the fact that you're making an international education project out of this mission. That's very important to me."

Astronaut Brian Duffy responded: "Mr. President, we find that using amateur radio is an excellent way of communicating with children all around the world, and we're also able to excite them by using space and science."

President Clinton concluded: "You may be on this mission, creating thousands of scientists for the future just by the power of your example and by this direct communication. I think sometimes we underestimate the impact that human contact in an enormously impressive setting like this can have on children across the world—not only those with whom you talk, but millions of others who will just see it and know that it happened." *TNX Westlink Report No. 653, July 15, 1993 and W5YI Report, Issue 13, July 1, 1993.*

Alkaline Batteries Rise From the Dead

Look out NiCd's (nIcads)—technology has given new life to spent alkaline batteries. Until recently, alkalines were considered throw-away types. Now Rayovac Corporation has unveiled an improved alkaline cell and recharger combo that blends the advantages of alkalines with those of NiCd's.

The low cost *Renewal* battery comes fully powered and ready to go. Rayovac says it lasts up to three times longer than a NiCd when new—however, the cycle-hours decrease to about the same as a NiCd after about 25 charges. The new battery also can hold a charge for five years (compared to three months with a NiCd) and shows no susceptibility to the dreaded memory effect of NiCd's. *TNX Electronic Products, No. 3, August, 1993.*

More Gadgets for Your MFJ-9020

Add features to this great QRP rig.

Robert W. Vreeland W6YBT

Like many hams, I just can't leave ham radio at home. The ideal traveling station should be lightweight and compact and should also have sufficient power for use with indoor antennas. The MFJ-9020 is the ideal basic building block for such a station. I have added an extra audio amplifier, some keying modifications and a lightweight power supply. For hotel room use, I built a short inductively-loaded dipole and a 20 watt amplifier to drive it.

Although the MFJ-9020 audio is quite adequate under normal conditions, some hams may want a little more volume. Therefore, I've added an LM380N amplifier using the circuit provided by the manufacturer (Figure 1). The LM380N has a gain of 50 but I wanted a gain of 10 so I added a five-to-one input divider consisting of a 22k resistor and a 4.7k resistor. The 0.02 μ F capacitor rolls off the high frequencies to reduce noise.

Photo A shows the method of mounting the amplifier using the MFJ speaker mounting screws. The original mounting nuts were left in place to serve as spacers, providing adequate clearance between the circuit board and the cabinet. Note that the

circuit board has been cut to fit the contour of the speaker. The strange tunnel on top of the LM380N is a sheet-copper heat radiator, grounded and soldered to pins 3,4,5,10,11 and 12. The white wire was disconnected from the speaker and reconnected to the amplifier input. The amplifier ground was connected to the speaker and to the original brown ground wire. Of course, I connected the amplifier output to the free speaker terminal. Power for the amplifier was taken from the two rear terminals on the MFJ power switch. The amplifier is used only with the loudspeaker. I have found that my old 2000 ohm Telex earpiece works much better than the earpieces designed for 8 ohm outputs.

The MFJ keying, although crisp and clean, was a little bit too solid for my taste so I decided to soften it, as shown in Photo B. This was done by bypassing to ground the output of the 78L05 regulator (U8), using a 47 μ F capacitor in parallel with a 220 ohm resistor. A 1N4005 protective diode was connected across the 78L05 as shown in Figure 2. This modification was done without drilling any holes and without removing the MFJ circuit board. The regula-

tor (U8) is located at the left near the front of the circuit board. I very carefully soldered a piece of #26 hookup wire to the regulator output lead on the top side of the circuit board. (A voltmeter was used to locate the 5 volt output lead.) The other end of this wire was connected to a terminal strip which I mounted on the MFJ antenna connector using one of the existing mounting screws. The 47 μ F capacitor and the 220 ohm resistor were then mounted on this terminal strip.

The manufacturer has thoughtfully provided a circuit board trace bringing the keyed 12 volt supply out just in front of the relay. The 1N4005 was connected between this point and the terminal strip. The keyed 12 volt bus was also brought out through a 100 ohm 1 watt resistor. This was connected to a red pin jack mounted in one of the unused holes on the rear panel. The jack is used to control my 20 watt amplifier for semi break-in.

The RF amplifier uses a pair of 600 volt Supertex VN0660N5s (Supertex Inc. 1225 Bordeaux Dr., Sunnyvale CA 94088-3607). High-voltage MOSFETS are nice because they can be powered directly from the recti-

Photo A. The audio power amplifier was attached using two of the original loudspeaker mounting screws. Note the tunnel-shaped sheet-copper heat radiator at the lower right. It is soldered to the LM380N.

Photo B. A double exposure showing the keyed RF envelope before modification (above) and after (below). The horizontal time base is 5 milliseconds per division.

Figure 1. An extra gain of 10 was provided by this audio amplifier.

Figure 2. Keying modifications. The pin jack controls the 20 watt RF amplifier for semi break-in.

fied and filtered 120 volt line without the need for a step-down transformer. The amplifier was built into a 4" x 6" plastic card-file box. Radio frequency transformers are used for the input and output to keep the high voltage inside where it belongs. High-voltage MOSFETs have been improved considerably in the last few years. Our amplifier runs at 50% efficiency and will withstand moderate antenna mismatches, but that is a subject for another article. A general discussion of high-voltage MOSFET amplifiers was published in *RF Design* (Vreeland, R.W.: "An Ultra Light-Weight Transmitter Using High-Voltage MosFets," August 1985, pp. 46-50) and in *QEX* (Vreeland, R.W.: "Notes On a Light-Weight Portable CW Transmitter With a Transformerless Power Supply," June 1988, pp. 11-13).

Add a Dipole

The station (Photo C) was completed by the addition of a 12 volt regulated supply (Edlie TE626-24; Edlie Electronics, 2700 Hempstead Turnpike, Levittown NY 11756-1443). Did I say completed? Well, not quite. What good is a station without an antenna? And how do you fit a half-wave dipole into a hotel room? The obvious answer is the inductively loaded dipole shown in Figure 3. The coils are wound on sections of 1-1/16" outside diameter PVC water pipe using Archer 278-1218 #22 gauge hookup wire. The method of anchoring the wire is shown in Figure 3. The wire was threaded down through one hole and up through the adjacent one. I fed the dipole through a 22-foot length of RG-58/U (Archer 278-971).

Tuning was done by adjusting the lengths of the end sections. A bowline was tied in each end to form a loop for supporting the antenna. The end sections for my antenna are 38 inches long as measured to the outer end of the loop. It is best to start with at least 42 inches of wire to allow for pruning. I have found the MFJ-207 SWR Analyzer to be indispensable for this purpose. When properly tuned the antenna will cover the entire tuning range of the MFJ-9020. The antenna should be mounted in the clear. Metal lath walls will cause detun-

ing, as will aluminum-backed insulating material.

The question of the possible existence of non-thermal RF health hazards has not yet been answered. Until it has, it would be best to hang the antenna a reasonable distance from the operator and to refrain from running high-power. As a former 75 meter AM mobile operator, I have been exposed

to moderate RF fields without noticeable ill effects. For this reason I take a fairly casual attitude toward moderate RF exposures. However, you should make your own decision. In these days when intelligent people worry about exposure to 60 Hz magnetic fields that are only one one-hundredth as strong as the magnetic field of the earth, how careful can you get?

Figure 3. Hook-up wire and PVC water pipe were used to construct this portable antenna. All measurements are in inches.

Photo C. Ready to go. The portable station was completed by the addition of a two-pound power supply (left) and a two-pound RF amplifier. Note the old reliable J-37 key mounted on a piece of circuit board.

Universal Automatic Minimum Power Control for AMTOR

Use just enough punch to get the job done.

by Ed C. Miller N7APE

Most of the digital communications in the ham bands is done at whatever power setting the operator chooses. I am sure most hams would prefer to operate at the minimum power needed, but with AMTOR it would require virtually constant adjustment.

The circuit described here was inspired by the automatic power control (for AMTOR) unit developed by Carl D. Gregory K8CG. It was designed for use with transceivers using external voltage control power adjust. The circuit presented here is for use with *any* SSB transceiver being used on AMTOR. It senses the same TNC signals as Carl's circuit, but uses that information to adjust the TNC audio level to the transmitter—and thus the power output. If no error signals are detected by the TNC, the transmitter power will be gradually reduced until an error is detected. It will then increase the output power level until no errors are detected. Thus, the transmitter power output will generally be at the minimum level necessary for reliable communication, meeting the FCC's requirement.

Although this circuit was designed for use with an AEA PK-232 TNC, it should be

adaptable to other units with only minor modification. And, because it controls the transmitter audio level, it should work with any SSB rig.

The main unit is on a small circuit board mounted inside the TNC. It interprets the error signals from the TNC. Its input includes ground, +5 volts, and the outputs of four of the TNC LED drivers, one of which enables the power control feature in the ARQ mode. All of the digital activity is conducted on this board. Its output consists of one shielded two-wire cable that plugs into the power control section, which is an L-pad with an FET for the output leg. This pad is connected between the TNC transmit audio and the transmitter audio input. One wire provides initial bias to the FET, and the other the control voltage to the gate of the FET. With this installation, no traces are cut, so the TNC can easily be returned to its original condition.

Control for this circuit is provided by the indicator driver ICs. If the TNC is in AMTOR mode, whenever an error is detected the RQ, PHASE, or OVER indicator driver is enabled. The voltage at pins 12 and 13 of the 4093B goes negative, which in turn causes pin 3 to also go negative. C5 is

gradually discharged, increasing the negative bias on the gate of the FET, reducing the loss in the T-pad consisting of R_a and the FET impedance. This increases the audio level to the transmitter, increasing its power output. When the power is raised to the point where no errors are detected, NAND Gate 2 will go positive, and the transmitted power will begin to gradually reduce. This constant automatic control of the RF output allows AMTOR usage at the minimum level necessary for reliable communication.

In any mode except AMTOR, the ARQ LED will not be lit, thus pins 5 and 6 of the 4093 will rise to +5 volts. Pin 4 will go negative, quickly discharging C4 and increasing the drain to source impedance of the FET to a very high value, causing minimum loss in the T-pad. This sets the transmitter output power to maximum in all modes except AMTOR.

Construction

The layout and construction of the main board is not critical. It can be mounted with metal brackets, using the two main board mounting screws. Care in mounting is important to prevent damaging the TNC board. Remove the bolts, then insert them in the

Photo A. Audio control unit (with cover removed).

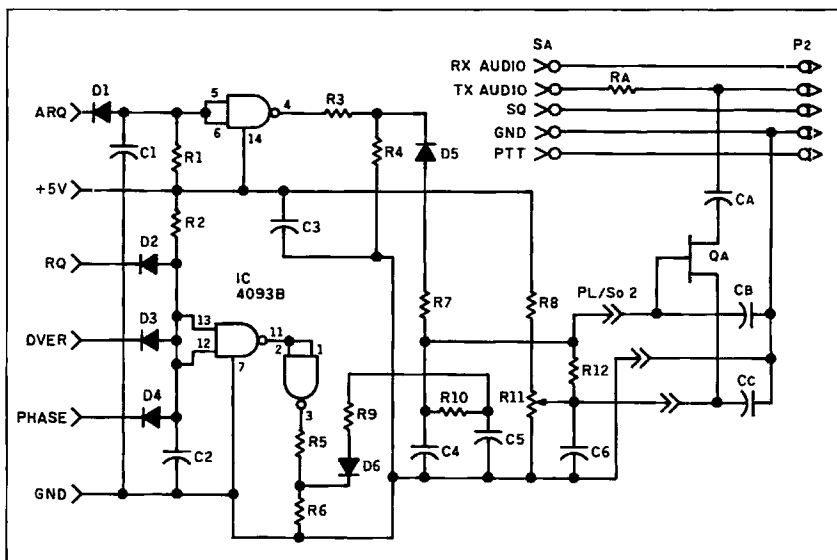

Figure 1. Schematic diagram.

Photo B. TNC rear view with unit installed.

Photo C. Suggested main board mounting.

mounting brackets. Place a mica (or other insulated) washer over the front bolt, and a small metal lock washer over the rear bolt, before re-inserting the bolts. *These washers are important* in preventing damage or the introduction of a short in the TNC board, and to provide its case ground connection.

The four status sensor wires are most easily connected to the appropriate LED negative connections on the indicator board. Extreme care should be used in making these connections as some of the LEDs have PC board traces very close to them.

The T-Pad unit was made of one-sided PC board, with a metal cover. It plugs into the RADIO 2 connector on the rear of the TNC, and the RADIO 2 cable plugs into it. This compact design and layout minimizes RF interference; however, it does require a steady hand and small tools for its construction. Of course, it is not necessary to have the cable-connector assembly made in a cable-end configuration. It would work equally well in

a small metal cabinet, with the male connector on it and a suitable cable to the TNC terminated in a five-pin female header.

Only one adjustment is required for setup: With the TNC operating in *any mode* other than AMTOR, adjust the trimmer resistor for

maximum audio output to the transceiver. It should be set just to the point where maximum audio output is reached.

In AMTOR mode, this unit will provide an output power-control range exceeding 20 to 1.

The Challenge of QRP

An introduction to low power operation.

by Michael Bryce WB8VGE

Ham radio has become pretty comfortable for most of us. Just about anyone can chase DX with a modern 100 watt microprocessor-controlled transceiver. *But just try that using minimum power!* That's the challenge of QRP. There's nothing like working a rare DX station with only 1 watt to sharpen your operating skills. But, of course, there's much more to QRP than DXing with low power.

What is QRP?

Well, it depends on what side of the fence you happen to be on. To me, QRP is RF output from a transmitter that is 5 watts or less, regardless of the input power to the transmitter. If you have 50 watts input and only 3 watts output, you're QRP to me. Your transmitter efficiency is really bad, but you're still QRP.

On the other hand, if you're working the CQ World Wide DX contest, and you're running a kW, by turning the amplifier off—thus dropping your power down to 100 watts—you're now QRP! In fact, let's take this one step further. Suppose the DX station you're listening to says, "QRP only please." Snap! Off goes the amplifier. You're now QRP and you make your con-

tact with 100 watts. That's far from operating with low power.

QRP is one of the internationally recognized Q-signals meaning: "Shall I reduce power?" Or: "Reduce power to _____ watts." Most hams have adopted it to identify low power equipment or operation. The QRP ARCI has formally adopted the power level of 5 watts as QRP. This is measured as output power from the transmitter. For really low, low power work, the term "milliwattling" has replaced the aged term "QRPP." The popular fire ball transmitter on 28 MHz proved it is possible to transmit coast-to-coast with 25 milliwatts! That's less power than the dial lights consume in most transceivers.

QRP is a great place to make new friends. QRP is a subculture within ham radio. Usually, when I tell someone I'm running QRP, the QSO changes from the usual, "Rig here is Kenwood and the weather here is warm" to a real chat with an interested human operator on the other end.

Building Your Own

Nothing in the world can beat the feeling of working a station using home-

brewed equipment—a QSO with gear you constructed with your own hands. The warm fuzzy feeling will last for days after the QSO is over. That's a feeling you don't get when operating the newest microprocessor-controlled SSB transceiver.

One of the most challenging and satisfying things a QRP operator can do is build his or her own gear. Best of all, you don't need to be a rocket scientist or an electronics engineer to build your own rig. In fact, QRP projects are especially suited for the neophyte in home-brew construction. Building a transmitter is relatively easy. Usually there's a wide tolerance range for parts, and most transmitters are built around straightforward circuits. Sometimes the transmitter is nothing more than a one-transistor oscillator coupled to an antenna. Only a handful of parts are required to produce 2 watts on most frequencies. You'll be astonished by the amount of DX you can work with just a spoonful of parts.

Because most QRP projects are simple, you usually won't have trouble finding parts for the rig. A well-stocked Radio Shack can supply you with all the parts required for a 75 meter CW transceiver. Companies like Mouser Electronics and

Photo A. The Ten-Tec Argonaut II is a full-featured QRP transceiver.

Photo B. Low power means portability. In this case, it's a solar-powered QRP wagon.

Photo C. Home-brew haven. Here is NR1A's QRP "ship in a bottle" setup.

Digi-Key will take small orders for one-secs and two-secs. Several hams have started their own companies supplying small parts just to the home-builder and the QRPer.

If you have a hard time getting the parts all lined up, several different companies furnish ready-to-go kits, too. Kits range from the very simple Roner by the G-QRP club, to the fully synthesized ARK-40 from S & S Engineering.

Sometimes the challenge of QRP comes from assembling a transmitter in the smallest possible chassis. I've seen rigs built in pill bottles, band-aid boxes, a match box, and even a Sucrets box.

Most QRP construction projects center around building QRP transmitters. There's nothing stopping you from rolling your own receiver either. The popular direct conversion receiver makes a perfect marriage for the QRP transmitter. A direct

conversion receiver is sensitive, and easy to build. Or you can go with several of the simpler superhet designs offered in 73. Many of these simpler designs rival the performance of much more complex receivers.

There's one more advantage to low power operation—TVI is almost unheard of with QRP.

Equipment for QRP Use

If you are a licensed ham, then you can operate QRP without spending one cent! All you have to do is reduce your output power and, snap! You're QRP. It really is as simple as that. You don't need to heat up the soldering iron if you choose not to, although you will be losing a gratifying part of the QRP environment.

All you need is already on your operating table—your HF transceiver. You don't need a special QRP rig to enjoy low power

operation, although there are commercial transceivers made especially for the low power enthusiasts. The popular Ten-Tec Argonaut II is a modern microprocessor-controlled QRP transceiver sporting all kinds of bells and whistles. The monobanders so popular today normally run QRP at 5 watts or so. Many commercial rigs, such as the ICOM IC-735, are easy to adapt to low power operation.

There's lots of used gear on the market, too. The popular Heathkit HW series of CW transceivers will still provide a lot of fun for very little cash layout. Used Ten-Tec Argonauts 505, 509 and the 515 provide 80-10 meter coverage plus SSB.

QRP and Other Frequencies

Alas, QRP is not only for HF use. Special QRP days have been set aside for the OSCAR satellites. Running too much RF on the uplink may damage

Photo D. The popular Heathkit HW-8 and HW-9 CW-only QRP transceivers. These are great fun!

Photo E. A simple home-brew transmitter like this will provide worldwide communications without you laying out large amounts of cash.

or shorten the life of the bird's battery system.

Then there's meteor scatter and mountaintopping using low power. It's possible to work numerous states under favorable conditions using 100 mW of RF on 10 GHz. QRP is very much alive on frequencies above 30 MHz.

Lower Your Electric Bill, Too

Do you own an HT? Then you've more than likely gone QRP at one time or another.

How many times have you said, "I've switched to low power. How is my signal into the repeater now?" Perhaps it was unknown to you at the time, but you had just

discovered two important facts about QRP. First, you don't need full power all the time to have dependable communications. Second, running QRP will stretch your battery's life, greatly expanding your ability to communicate longer without plugging in.

Because QRP equipment is normally

QRP Q&A

Ever since my Novice days, I've been running QRP. I've collected files full of letters from hams all over the world asking about low power communication.

There seemed to be a pattern developing in the questions, so I picked out some of the more common ones. Here they are, in no particular order. Enjoy!

What is QRP?

QRP is a term adopted from the international RQS signals meaning to reduce power. Hams have taken this term and its meaning to be low power. Generally, QRP is 5 watts or less from the transmitter, regardless of the input power to the transmitter. If you hear someone on 40 meters calling CQ QRP, he (or she) is calling for a low power station. More than likely, they will be using low power, too.

What is QRPp?

QRPp is the older term for RF power of 1 watt or less. That extra small "p" meant really low, low power, generally under 1 watt. That term has been replaced by the term "milliwatt." While it may be hard to believe, you really can work around the world with an output power of 50 milliwatts! There have been many hams working DXCC with only 100 milliwatts to the antenna. It is hard to do, but not impossible.

What are the most popular QRP bands?

There really is no one band more popular than the others. You'll find QRP operation everywhere from DC to light. But, some consider the 40 meter band around 7.040 MHz to be QRP Central. You can also find some action on 7.035 MHz and 7.060 MHz. In the winter time, when summer QRN is down, 80 meters is very popular during long cold nights. There is QRP activity on 160 meters, too.

The 30 meter band is a QRPers' delight! Try 10.106 and up for low power signals. Then, let's not forget about the 20 meter band either. This is by far the most popular ham band when it comes to working DX. Low power operation used to be located around 14.060 MHz, but alas, other forms of digital signals have been moving down, overtaking the QRP-calling frequency. Check the entire band for QRP operators—they're everywhere on 20. You can find QRP signals on 17, 15, and 10 meters, too.

I'm not into CW. Can I still operate QRP?

CW is by far the most popular mode of QRP operation. It's partly because CW transmitters are easier to build than SSB rigs. With CW, you get more bang for the watt, too. But, QRP is not only CW, it's any mode you want to use, including FM or SSTV. Remember: QRP means low power—not CW only.

Do I need to change rigs or equipment to operate QRP?

Of course not! Most of today's rigs can be easily turned down from a front-panel control. You'll end up with low transmitter efficiency, but you won't have to spend a dime.

How about antennas? All I have is a simple dipole.

No matter what power level you use in amateur radio, the better the antenna, the better your signal will be. Use a good grade of feedline and get the antenna as high as possible.

I enjoy a good contest now and then. How can I compete with other stations if I run only 2 watts?

Most of the major contests, such as the CQ World Wide DX contest, Sweepstakes, and even Field Day, have special low power sections. You only compete against others within the same power class. You don't have to worry about the guy running a kW because you are not in the same class.

I know many QRPers like to build their own gear. I'm not much of a builder. Can I purchase a commercial QRP transceiver?

It's too bad you don't like to build your own gear. You're missing out on a lot of fun. But yes, you can purchase a commercial QRP transceiver. Ten-Tec

markets their Argonaut II QRP transceiver with all the good stuff we're used to seeing in today's gear. There are many other monoband rigs, such as the MFJ units, available. Tejas RF sells their popular Backpacker II fully assembled and tested.

Almost all of the circuits I've seen in the last few issues have been solid-state transmitters. How about us guys with boxes full of tubes?

It is the 1990s and today's technology is solid-state and microprocessors. But, if you want, you can still use a vacuum tube in a QRP transmitter. The best place to look for a circuit is in an old copy of the *ARRL Handbook*. Begin looking with the early '70s and work your way back to the '50s. Parts for those circuits may be next to impossible to locate, unless you have a really big junk box.

Can I operate packet or AMTOR?

Yup! Sure can. Again, QRP simply means low power. Any mode of communications is suitable for QRP, with the exception of moonbounce! I've had some great QSOs using AMTOR with less than 4 watts PEP.

Are there any QRP clubs to join?

Yes! As a matter of fact, I'm the publicity manager for the QRP ARCI, the largest QRP club in the world. If you would like to have one of the info kits, all you need to do is send \$2 to me (2225 Mayflower NW, Massillon OH 44646) and I'll have one in the mail to you the next day.

The Michigan QRP Club also serves low power enthusiasts with the *5-Watter*. Published four times a year, *5-Watter* makes for great reading.

There is also the G-QRP club. Based in England, they publish *SPRAT*, which is full of construction projects.

I like to collect awards. Can I still do so with QRP?

Yes! There are many, many awards issued just for QRP operation. These range from a WAS with QRP endorsement to the Miles Per Watt Award. Many other contests also provide a special QRP award such as the ARRL's Sweepstakes or the CQ World Wide DX contest.

What are some of the limits of QRP?

QRP is not push-button communications! There will be times when your 2 watts just won't cut it. Band conditions, QRM, sunspots, and QRN all take their toll on a 2 watt signal. There will be times when your 2 watts or RF won't be enough to make a contact.

Some modes don't seem to work as well as others. SSB, for example, is much harder to do with QRP power levels because everyone likes that *armchair copy*. You won't be armchair copy most of the time on SSB.

AM phone is really tough on QRP! It's possible to work coast-to-coast with AM phone on the 10 meter band using QRP, but on 75 meters and 40 meters it's not going to fly.

I'm on a limited budget. Would QRP be the best way to go to enter ham radio?

QRP means low power, not inferior equipment! Don't get the two mixed together. You could pick up an HW-7 at a hamfest for under \$50 and have a ball, or you could drop five grand for an ICOM-785, turn the drive down, and run QRP, too. While it is true you can pick up a brand-new rig such as the MFJ QRP monoband rig for about \$150, compared to about \$1,000 for an entry-level 100 watt rig, going QRP would save you money, but at a cost of only one band and being stuck with CW only.

If I start to operate QRP, what's in it for me?

No matter what you do in life, you get out what you put in. QRP really boosts your ego. Breaking a DX pile-up with 2 watts will keep a smile on your face for weeks. Working the West Coast with 1 watt from a transmitter you put together with your own hands is one of the best ways to generate those warm fuzzy feelings.

If you're tired of the quick, "Hi. Rig here is blank. Weather here is blank" type of QSO, give QRP operation a try. And if it's nothing else—it's *FUN!*

much smaller, power requirements are easily met with small batteries. A QRP transceiver is ideal for taking ham radio with you. You can easily carry a complete HF rig, including batteries, in a backpack. Hiking, camping or even white water rafting takes on a whole new meaning now that ham radio is aboard. There's also the possibility ham radio could save a life or two while you're out camping.

Battery power is all you need for worldwide communications from your home, too. In fact, most QRPers enjoy operating their gear from batteries. Solar power and QRP operation go hand-in-hand to supply all the energy requirements of even the busiest ham.

During a natural disaster, your QRP transceiver may be the only source of communications from the disaster area. During electrical outages, running your ham gear QRP style takes on a whole new meaning.

Getting Started

The best way to start in the fascinating world of QRP is to simply reduce your transmitter power a little bit at a time. This gets your feet wet without too much pain. You can make a contact at, say, 100 watts and then slowly reduce your drive until you're at only 50 watts. Drop the power down again, and then again. You'll really be surprised as to how low you can get before the signal becomes unreadable.

QRP is not push-button operating! If you're used to making a contact on one call, then an adjustment in thinking is in order. Anyone can work station after station, many times over, using less than perfect antenna systems with 100 watts. That's not so with QRP operating.

If you're used to getting 599 reports, you'd better be ready for lots of 349 and 239 reports. With 100 watts, you're always

59 on phone; with QRP, you'll be QRZ? QRZ? the station calling. Working WAS with QRP SSB is a real challenge! But, then again, many, many times, I've been 599 with 1 watt to the antenna. That's part of the thrill of QRP, you never know what will happen.

Efficiency is the Key to QRP

I know you've heard it before, about the guy who works DX with a set of old bed springs. Well, that's not going to cut it with QRP operation. You need the best antenna system you can muster up. Don't get me wrong, you don't need an antenna farm containing enough aluminum to build a B-52 to operate QRP successfully—but it wouldn't hurt, either!

"During a natural disaster, your QRP transceiver may be the only source of communications from the disaster area. During electrical outages, running your ham gear QRP style takes on a whole new meaning."

Antennas are placed as high in the air as possible. Only the best quality feedline is used between rig and antenna. Resonant antennas instead of trapped multiband antennas provide the QRPper with improved efficiency. Anything you can do to increase efficiency will improve your chances of making a solid QSO.

Operating Hints

There are many techniques for successful low power operation. Sometimes one particular technique will work this time, and then fail the very next day. Here are some of the many techniques I've found to be helpful in keeping the logbook filled with QSOs.

Get to know the bands and how they operate. Use propagation aids to find out what band will be open and for how long. Why, you might even want to find out how to figure out the propagation charts in the back of 73. There are disks full of computer programs to help you determine the MUF, or Maximum Usable Frequency. Using these programs will improve your QRP score. If the bands are dead, you might as well heat up the soldering iron and work on a project; QRP and crappy bands don't mix together well.

Tune the band looking for stations calling CQ. Answering the loudest station sending CQ helps, too. Another method is tail-ending a QSO. You tune around until you find a QSO in progress. After the two stations have signed, you call the loudest one. Most of the time you'll hear your call coming back. This is by far the most popular method of QRP operation.

If you only want to fill up your logbook, then work the state-side contests. The West Virginia QSO party will provide you with lots of quick QSOs. Why? Because you're an extra two points to the other station. You don't have to be in the contest to work contest stations.

Here's a strange one. Check out dead bands for activity. You never know: I've heard DX stations calling CQ on supposedly dead bands. It only takes a few minutes to tune around the high end of 10 meters for a quick check, even if the computer says the band is dead.

Anyone Can Operate QRP

A different frame of mind is all that is needed. It's the idea of doing more with less. QRP operation is surprisingly easy, fun, and a whale of a good time. It may be exactly what you need to put some snap back into ham radio.

Price Class: \$159.95 plus S&H

Operating QRP has always been a lot of fun for me. Operating QRP in the woods all by yourself, with a rig you built with your own hands, is a delight beyond words! You can join in the fun for yourself with the Backpacker II 40 meter transceiver from Tejas RF Technology.

The Backpacker II

The Backpacker II is based on the popular W7EL direct conversion receiver. The Backpacker II is an 1992 updated version using a doubly-balanced diode ring mixer. The Backpacker II has replaced the transistors used in the original version with low noise op amps. The results are outstanding! An improved method of frequency control is the heterodyne oscillator and mixer. In the Backpacker II, the VFO does not run at the same frequency as the transmitter. The VFO instead operates between 6.0 and 6.2 MHz in a Hartly oscillator configuration. This prevents RF from getting into the VFO and causing frequency shift or drift during key down. You get a 200 kHz segment of the 40 meter band with the VFO.

This method also allows the Backpacker II to operate on any single band (including 20,

17 and 15 meters) without losing stability due to VFO drift at the higher operating frequencies normally used in a direct conversion receiver. You could put the Backpacker II on any frequency by changing the output filters and tuned circuits. To make a band change, you'll need to change the crystal in the heterodyne oscillator and change the tuned circuit following the mixer. The tuned circuits in the amplifier stage will also need to be changed and the Backpacker II retuned. A band change kit is \$10 and includes the 11 parts required for a band change. In a way, the Backpacker II is really a monoband CW transceiver for 40, 30, 20, 17 and 15 meters. Of course, you can have only one band at a time.

A RIT circuit rounds out the VFO control scheme. The RIT control features a center-detent position allowing easy zeroing of the RIT. You cannot turn the RIT function off. The range of the RIT is ± 1.5 kHz. There is a spot control to find your signal in the receiver's passband.

The Receiver

The Backpacker II uses the Mini-Circuits Labs TUF-1 doubly-balanced diode ring mix-

er. Along with this mixer, additional filters reduce interference from the 40 meter broadcast stations. If you've ever operated a direct conversion receiver on 40 meters at night, you'll really relish the front end in the Backpacker II.

A low noise amp is used as an AF preamplifier. The other half of the op amp acts as an active low-pass filter designed to allow fatigue-free CW listening.

SSB Sounds Good, Too!

An LM380 audio amplifier gives the Backpacker II plenty of audio to drive a small speaker. If you're used to a direct conversion receiver with a wimpy LM386, you'll be in for a nice surprise at the amount of audio coming from this little rig. You can get a maximum of 2 watts of audio into an 8 ohm load with the LM380. A speaker is not included in the kit, but there is room-a-plenty to add one to the case if you wish. A front-mounted 1/8-inch jack for a headphone is included. In fact, all the controls for the Backpacker II are mounted on the front panel.

A second op amp provides an active CW bandpass filter. The two-position CW filter provides a 180-cycle bandwidth on CW-1 and a 110-cycle bandwidth on CW-2. Both filters are peaked at 750 cycles. You can set the bandwidth to the wide position, effectively removing the filter from the audio line. With the filters out, the bandwidth is approximately 2.2 kHz wide. A sidetone is injected to the audio channel and its injection level may be set to your own liking. The sidetone volume tracks along with the audio control.

The Backpacker II uses differential keying. This is a fancy way of saying the rig shapes the CW signal and switches over to transmit before the RF reaches the antenna. The time sequence differential, keying properly and timely, performs several T/R functions. The Backpacker II keys very nicely. It has electronic QSK keying, making for silent QSK keying with no relay chatter breaking the quiet of the woods. The receiver draws 25 mA with no signal to about 100 mA with reasonable volume. The entire Backpacker II weighs in at a mere 23 ounces.

The Transmitter

The transmitter is made up of one driver stage and the PA. The VFO signal is applied directly to the driver via a trimmer. This pot can be used to set the output power of the

Photo A. The Backpacker II is at home in the woods. The 40 meter version is pictured here with a 10 watt solar panel and a 6.5 amp/hour gel battery providing the juice.

Backpacker II. A 2SC799 provides the bang for the transmitter. The Backpacker II will produce about 2 watts output on 40 meters, more than enough to provide worldwide communications. The PA is protected against high SWR by a 36 volt zener diode. The transmitter output is fed into a half-wave low-pass filter to suppress any harmonics. The transmitter requires 12-14 volts at 300 mA.

The transmitter uses an RCA phono jack for the antenna. Thinking Bill was just being cheap. I wondered why he did not use an SO-239—until I read through the manual. The silk-screen for the antenna jack is applied low enough to allow the builder to add an antenna jack of his choice. You can use a SO-239 or a BNC connector if you wish. Of course, you can always just use the RCA jack supplied for the antenna.

Putting It Together

My Backpacker II came already assembled and tested so I did not have the pleasure of building it myself. For those looking for a diversion for the weekend, the Backpacker II is going to make you feel right at home with the soldering iron. However, the Backpacker II is not for someone building their first kit. A good basic knowledge of soldering and knowing what a diode looks like and how this guy goes on the PC board is a must. All coils come fully wound and ready to be installed.

The case needs mentioning, too. It's solid 5052 aluminum with epoxy silk-screened letters. They're tough enough to be washed with Formula 409 and still remain on the aluminum. Thankfully, there are no holes in the cabinet for dirt, twigs or critters to move in.

There are many wires connecting the three PC boards together. It would be very easy to get messed up and put the wrong wire

in the wrong hole. A highlighter pen would be very useful in keeping track of what wire goes where.

The manual contains all you could ask for in getting your Backpacker II on the air. There's even a section on antennas. There is a complete parts list and a set of oversized PC parts placement diagrams. Full adjustment and set-up procedures are included. If you can't get it to work, there is also a trouble-shooting guide to help you track down the trouble. The Backpacker II comes with a 90-day parts warranty.

Out in the Woods

Running the Backpacker II in the woods proved to be a lot of fun! I used a random wire for an antenna and a small Ten-Tec antenna matcher. A small 10 watt solar panel and a 6.5 amp/hour gel battery provided the power.

Using a high performance direct conversion receiver is hard to describe. Signals seem to POP out of a noiseless background. There are no birdies to contend with and no phase noise from a PLL to get in the way.

Photo B. Under the hood of the Backpacker II you can see the transceiver's three vital PC boards.

The time sequence differential keying proved very nice and the QSK worked quite well. With a nominal 1.5 watts out, there is enough bang to make things interesting without fretting about the batteries going flat.

I made contacts all up and down the East Coast using the Backpacker II. It's a solid 40 meter transceiver that I know you'll have a good time with. It's even more of a delight when you're working the world from your own stump in the woods.

The RASER Revisited

How this superior HF dipole antenna can be improved.

by James E. Taylor W2OZH

The original article on the RASER ("The RASER: A Novel Wire Antenna System," by James E. Taylor W2OZH, 73 *Amateur Radio Today*, September 1992) showed how a dipole can be extended to provide enhanced gain with a length much less than the normal two half waves in phase. This was accomplished without the need for either a high-impedance feedline or an external antenna tuner. Both end-fed and center-fed options were described. This article will show how I increased the gain of the RASER appreciably while using an improved coupler circuit, which also provides decreased feedline radiation.

The RASER Concept

The center-fed RASER for 75 meters is comprised of a dipole lengthened by self-resonant Divided Coherent Radiator (DCR) sections on either side of the center feed point. Since the RF currents in the adjacent DCR sections are essentially equal and in-phase, the antenna shown gives a power gain of roughly a factor of two over the normal figure-eight pattern of a classical dipole. Such a 20-section RASER is shown in Figure 1. Each DCR section is comprised of a chosen length of wire, which acts as an inductor, and a capacitor which, together with the inductor, forms a series resonant circuit. The wire length was chosen to be 57 inches and the corresponding capacitance was 750 picofarads. Figure 2 shows the scheme for mounting the capacitors, which were potted in insulating foam. I adjusted the antenna to resonance by changing the lengths of the two terminator wires and by selecting the capacitance in the coupler unit, shown schematically in Figure 3. The coupler unit used a bifilar-wound powdered-iron toroidal transformer for impedance matching. This 20-section RASER was used at W2OZH for over a year with outstanding results.

How Can the RASER be Improved?

Critical review of the above design gives rise to three constructive questions:

1. Could the common-mode shield radiation be decreased by placing the shield connection at the tap on the transformer, to bring it closer to the electrical center of the

balanced radiator?

2. Could the capacitor in the coupler unit be eliminated by direct connection to the feedline?

3. Could the inductive component then remaining at the feed point be counteracted by increasing the capacitive reactance of the terminators, i.e. by shortening them? If so, can the number of DCR sections then be increased to improve the gain, without a net increase in the overall length of the antenna?

I investigated each of these possibilities, and made the following improvements in the design.

The Balanced Coupler Circuit

The previous coupler circuit, shown in Figure 3, which involves a simple autotrans-

former connection, can be redrawn as in Figure 4 to clarify ground relationships. Referring to Figure 4, the two halves of the RASER radiator naturally comprise a balanced symmetrical circuit with a virtual ground at the center. It is apparent that the shield connection is not isolated from RF ground and should ideally be placed at this center rather than at the right-hand side as shown. The unbalanced feed system shown does not discriminate against common mode coupling with its attendant feedline radiation. The circuit arrangement shown in Figure 5 would improve this situation by placing the shield connection electrically much closer to the natural virtual ground of the radiator.

I experimented with this change (Figure 5) and found that the RF current on the

Figure 1. 20-section RASER antenna (center-fed).

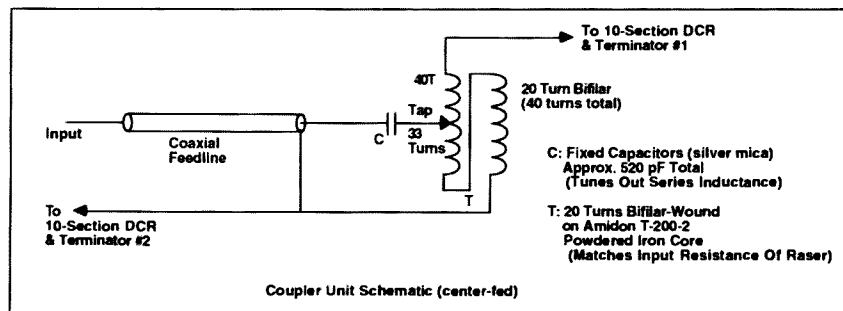

Figure 3. Coupler unit schematic (center-fed).

Figure 4. Original coupler unit (redrawn).

Figure 5. Original coupler unit—balanced input.

Figure 6. Improved balanced coupler unit (no capacitor).

shield of the coax, as measured by an MFJ H-field Antenna Probe, was decreased substantially. Resonance measurements using a noise bridge led to changes in the value of capacitance required for resonance. This is consistent with the measured reduction of common mode coupling, further confirming that the answer to question 1 above is "yes." During these experiments I noticed a prominent resonance point some 100 kHz below the desired frequency of 3.953 kHz. This led to experiments answering questions 2 and 3 above.

Elimination of the Coupling Capacitor

As an experiment, I replaced the coupling capacitor by a direct connection, as shown in Figure 6. This leaves a substantial uncompensated inductive reactance at the feed point, which lowers the resonant frequency

of the system. The measured resonant frequency of the 20-section RASER with the terminator lengths of 51' 4" was lowered to below 3.7 MHz. Thus, the answer is "yes"—the capacitor can be eliminated.

Re-Resonating the Radiator

I then made the terminators incrementally shorter, which raised the measured resonant frequency of the radiator. Since the terminators had been made shorter I was able to add more DCR sections for greater gain without any increase of the overall space required. These experiments showed the desired deep resonance nulls on the noise bridge with very satisfactory bandwidth. Thus, the answer to question 3 above is also "yes"—the capacitor can be eliminated and the number of DCR sections can be increased.

Thus, the procedure which I followed was first to add DCR sections and then to adjust resonant frequency by changing the length of the terminators. I found that increasing the number of DCR sections to 12 on either side of center and changing the terminator length to 29 feet gave a deep resonance null (signifying a pure resistance) on the noise bridge at a frequency slightly above 4.0 MHz. This indicated that, for my available space of some 200', I could increase the number to 30 DCR sections (15' either side of center). The final RASER design is shown in Figure 7.

The Final Design Values for Two RASER Radiators

At W2OZH, a two-element phased array is used so it was necessary to optimize the

Figure 7. Balanced 30-section RASER—(center-fed).

lengths of two parallel RASERS. This simply involves adjusting the lengths of the two identical terminator wires until the desired frequency, in my case 3.9535 MHz, is approached. The final design values are shown in Table 1.

The differences between the two RASERS are probably due to the proximity of nearby buildings, trees, etc. However, these measurements indicate a level of variation to be expected in other installations of this outstandingly effective antenna.

Results

The experiments described produced the serendipitous results of a simplified design which yields improved performance. The use of a coupler connection which is balanced to ground measurably decreases the

feedline radiation due to common mode coupling. The elimination of the coupling capacitor simplifies resonance adjustment and the attendant shortening of the terminator wires permits the insertion of 50 percent more DCR units to further increase the gain of the radiator.

The modifications of the RASER described above were confined to the center-fed version because this configuration is suitable for my site. However, similar changes can be made in the end-fed arrangement. The procedure would only involve reversal of the input connections to the transformer in the coupler, elimination of the capacitor by direct connection, and experimental adjustment of the single terminator wire. All other adjustments should remain as described in the original article. Although the

Table 1.

Terminator Lengths	Tap Position	Resonant Frequency
27' 5" (east radiator)	25 turns	3.954 MHz
26' 2" (west radiator)	26 turns	3.948 MHz

parameters indicated above are for the 75 meter band, the design can be modified for any other band. This would involve using the steps of design described in the original RASER article, but scaled for the chosen frequency of operation. It would be interesting to see the performance of a RASER designed for, say, 20 meters, where a high gain, linear beam antenna could be realized for point-to-point DX communication.

I have now used the 30-section RASER design in a two-element phased array for several months with even better results than for the previous 20-section version. It is my perception that the directivity has been improved and the large capture area of the system for reception brings about a dramatic decrease in fading of the signals. Results experienced when I have occasionally worked QRP stations lead me to believe that this would be an outstanding antenna for that application.

I wish to acknowledge the patience of many hams who have given signal strength comparisons as I switched several available combinations of RASER elements. 73

INTRODUCING THE UNIVERSAL M-400

A totally new concept in code / tone readers!

- A RTTY-reader and tone-decoder in one!
- Easy to read two-line 40 character LCD.
- No computer or monitor required.

- Baudot
- SITOR A/B
- ASCII
- SWED-ARQ
- FEC-A
- FAX
- POCSAG
- GOLAY
- ACARS
- DTMF
- CTCSS (PL)
- DCS (DPL)

Forget the limitations you have come to expect from most "readers". The self-contained Universal M-400 is a sophisticated decoder and tone reader offering an exceptional range of capabilities. The SWL will be able to decode Baudot, SITOR A & B, FEC-A, ASCII and SWED-ARQ. Weather FAX can also be decoded to the printer port. The VHF-UHF listener will be able to copy the ACARS VHF aviation teletype mode plus GOLAY and POCSAG digital pager modes. Off-the-air decoding of DTMF, CTCSS (PL) and DCS is also supported. The M-400 can even be programmed to pass only the audio you want to hear based on CTCSS, DCS or DTMF codes of your choosing. The M-400 can run from 12 VDC or with the supplied wall adapter. The American-made Universal M-400 is the affordable accessory for every shortwave or scanner enthusiast. **Only \$399.95 (+\$6 UPS).**

The MFJ-451 Morse Keyboard

A perfect fist, right out of the box.

As an avid CW operator who uses this albeit archaic mode more than any other, I was overjoyed to see MFJ introduce their new MFJ-451 Morse Keyboard; finally, an affordable, state-of-the-art product that will fit into nearly anyone's station and budget! Even better, this item is almost totally self-contained and requires no connection to a computer to make it work, allowing die-hard CW ops like me to take it portable. (I say "almost" self-contained because it does require a source of 12 VDC power and cannot be operated from an enclosed battery—too bad. Its current consumption of about 250 mA DC—3 watts!—would not allow a little 9 volt Duracell or Energizer to last very long, anyway.)

I don't know about you, but I'm really turned off by new products that take hours of

set-up time and pouring through instructions to operate. This is probably why I only use computer software that is so intuitive it requires no more than loading in a disk to get going. The MFJ-451 is perfect for those of us who like to just "plug and play." Although it is supplied with a well-written, nine-page instruction manual, reading the instructions is *not* prerequisite to using the keyboard as soon as you take it out of the box. I had mine on the air within about two minutes after the UPS shipment arrived!

The MFJ Morse Keyboard is actually two items: The keyer, which is enclosed in a tiny 1-1/4" x 3-1/4" x 4-1/4" (HWD) black metal case that also contains the power ON-OFF switch, sidetone monitor volume adjust control and monitor speaker; and the keyboard,

which is a standard PC-AT keyboard with a normal five-pin DIN connector (just like any PC keyboard). The keyboard supplied by MFJ is made by Mitsumi Electric Co. in Malaysia and is of very high quality with an excellent "feel," but *any* AT keyboard will work as well. The manufacturer warns that use of an XT keyboard, or using an AT keyboard switched to the "X" mode, will *not* work and may even damage the keyer, so if you don't already have an AT-type keyboard, I'd surely recommend using theirs. Although there are other differences, an AT keyboard is most easily recognized by its row of 12 function keys (F1-F12) across the top, above the standard typewriter keys. (XT keyboards ordinarily have just 10 function keys F1-F10, located on the left-hand side of the keyboard,

Photo A. The MFJ-451 Morse Keyboard Keyer is primarily a keyboard, as you can see. The keyer electronics is all inside the tiny black box. The front panel contains only a volume control, status indicator LED, and sidetone volume control.

arranged in two vertical columns.)

The keyboard supplied by MFJ with the Model 451 keyer has abbreviated operating instructions describing the 12 function key operations printed on a label placed in the upper-right corner of the keyboard. A key overlay or a long label placed above the 12 function keys might be nicer, but this thing is easy to get used to, and once you've used it for an hour or so, there's no longer any need to refer to the label, anyway.

The keyer unit itself is so small and lightweight that it could probably be "velcro" attached to most rigs in an out-of-the-way location. You really don't need to access its two controls (ON-OFF and sidetone monitor volume level) at all if your transmitter or transceiver has its own sidetone and you switch power to the keyer along with your radio. Although MFJ doesn't mention this in their instructions, you could also run the keyer off a regulated source of 5 volts DC with a minor rewiring job internally: Just rewire the "output" terminal of the 7805 regulator chip U5 to the "DC input" jack on the rear panel of the keyer, and it will run on 5V; however, if you do this, be sure to *never* connect that jack to a higher-voltage source, or you'll risk destroying the 80C32 keyer chip U1!

The keyer has just five rear-panel connections: Keyboard In (five-pin DIN), Power In (12 VDC, using a standard 2.1 mm coaxial plug with center positive); Paddle In, which allows use of a conventional three-terminal electronic keyer paddle, should you decide at some times to not use the keyboard (3.5 mm stereo "mini" phone plug); External Speaker Out, to override the internal monitor speaker (standard 3.5 mm monaural "mini" phone plug); and Keyer Out, which is the keyed line to your transmitter (RCA phono plug). The keyer output can be arranged to key both positive and negative-polarity transmitters and comes factory-wired to support positive-keyed solid-state transmitters. MFJ calls this "direct" keying (as opposed to "grid-block" negative keying, used in many older, tube-type rigs) and uses a VN10KM power FET as the internal keying switch—a good choice of device for the application.

Like all keyboard keyers I've seen, the keyer uses a buffer between the keyboard and the keyed output line, so you can "type ahead" of your actual sending speed, up to a maximum of 200 characters. Adjusting the keyer sending speed to be precisely the same as your typing speed will result in "real time" sending, which is very tricky at best and leads to jerky-sounding sending. It is much better to set the sending speed to be somewhat slower than your actual typing speed, and use the "type ahead" buffer to take up the slack. Since I type at 75-80 wpm (375-400 characters/minute), and nobody can really copy code that fast, I found it convenient to set the sending speed (accomplished by depressing F3 and then typing a two-digit speed from "05" to "99" wpm) at a normal conversational rate of maybe 20-30 wpm. Then I happily type away at my more comfortable, faster speed. For a real typist, this takes no getting

used to at all, but for a "hunt and peck" typist, this might take a bit of self-training.

To let you know that you're running out of buffer memory, the keyer sidetone frequency lowers in pitch when the buffer is filled to 180 characters. When the 200-character buffer is completely filled, the sidetone will sound an error message with all additional keystrokes. Pressing the "escape" key (ESC) on the keyboard while it is sending your type-ahead message will immediately stop the keying and clear the buffer. Pressing the "pause" key (upper right-hand corner of the AT keyboard, next to "scroll lock") will stop the message, allow you to insert additional text using a paddle key, and *not* clear the remaining buffer memory; then, pressing the "escape" (ESC) key will continue playing the buffer memory where it left off before pressing "pause."

In addition to the sending speed being adjustable by keyboard command as described earlier, additional adjustments may be made for sidetone frequency (F2); keyer weighting (F4); two 100-character messages which may be preprogrammed (F5 and F7); playing the contents of those two memories (F6 and F8); putting your transmitter into the "tune" mode

Photo B. The rear panel of the MFJ-451 keyer box contains I/O ports for: 12 VDC in; keying output; external speaker; paddle input; and keyboard input.

by sending continuously (similar to closing a hand key) by using another function key (F1); and even converting the keyboard space bar to a hand key (F12). When you're entering text into one of the memories, your keying sounds on the local sidetone monitor but the keyer does *not* key your transmitter. Another way to practice using the keyboard while it is connected to your transmitter, when you want to hear what you're keying in on the sidetone speaker but don't want the keyer to actually send a signal over the air, is accomplished by using the Key Output Disable function (F9). Two other function keys, F10 and F11, are used for serializing messages, such as would be required in the ARRL Sweepstakes and some other contests.

The MFJ Morse Keyboard is set up to send not only regular alphanumeric characters (A-Z and 0-9), but many amateur radio prosigns as well. These include popular prosigns like BT (double dash, used between thoughts instead of a period); HH (eight dits, thought to indicate "error"); AS (standby); AR (end of transmission); SK (end of contact); as well as

many not-so-popular ones like AL (new paragraph); SX (dollar sign, \$); KN (response expected from one station only, directed) and so forth. To use the prosigns effectively, one must pretty much memorize which single key sends them. For example, BT is sent by using the = (equals sign) key; the error message (eight dits) is sent by using the @ key; AS is sent by using the & (ampersand) key, etc. Some of these prosign assignments aren't particularly logical and it takes some getting used to, but the limitation is the AT keyboard, of course. Again, a keyboard overlay provided by MFJ might help users remember these key assignments. Regular punctuation signs like . (period); , (comma); / (slash bar, used to indicate portable operation); and ? (question mark) use the regular keys that are so labeled.

The MFJ-451 also includes three "embedded command" functions which are addressed with two keystrokes rather than a single one. For the embedded commands, CTRL (the Control key, located at the lower left and right of the AT keyboard, below the SHIFT keys) is used along with the keys for L, P or S, depending on which embedded command feature you are using. CTRL-L creates a repeated message, like a beacon identification or a CQ, which, after addressed, will play repeatedly until stopped by pressing ESC (escape). CTRL-P allows the insertion of a timed pause within a message. CTRL-S allows the insertion of a sequential serial number within a message, and, to avoid wasting time, sends the letter "N" for nine and a "T" for zero, just like experienced CW operators do. These functions are all quite handy.

The message memories addressed by F5 and F7 (and played back by F6 and F8) are limited to 100 characters each, which is more than sufficient for anything I could think of. So that you needn't count characters when programming these memories, the sidetone pitch lowers in frequency when you type past 90 characters, letting you know you only have 10 characters left in memory.

The Morse Keyboard operates as naturally as a typewriter and does not require a lot of thinking during operation. If you make a typing mistake, simply press the BACKSPACE key and the keyer will erase the last character typed and allow you to make a correction. The space bar inserts a word break space in the text, just like you are used to doing with a typewriter or word processor. The SHIFT key enables upper case characters if applicable. (In alpha text, the SHIFT does nothing; but punctuation and prosigns can be addressed and changed with the SHIFT key.)

How does it work on the air? Like a dream. As I said, this product takes literally zero familiarization period for an experienced typist, and operates intuitively enough for immediate use right out of the box. I didn't get around to reading the instruction manual—which is imprinted with the bold warning "Always Read All Instructions Before Operating New Equipment" on its cover—until after my first couple of dozen QSOs. This is the perfect device for those who, like me, enjoy instant gratification

with a new "toy." Because I hadn't used any kind of keyboard keyer in years, I was just a bit shaky during my first few contacts and sent apologies in advance for any mistakes I might make: "Bear with me, OM, I'm using a brand-new keyboard keyer, so pardon my sending." No excuses were necessary, though, as I had it all under control right from the start. Everyone complimented my wonderful "fist," although I wasn't doing anything, just happily typing my thoughts on a keyboard as I've done since I was a kid in grade school.

Dream On Department

When a product is this easy to use and so reasonably priced, I feel badly about asking for anything more. But nothing is perfect, and we hams are impossible to please, so here goes. The MFJ-451 does not make use of the numeric keypad on the right-hand side of the AT keyboard, so numbers must be sent using the numeral keys on the main QWERTY keyboard (top row). For those of us who are really used to using calculators, this is a tiny handicap: I'd rather use the numeric keypad and wish it were enabled by the MFJ firmware. Next, rather than two 100-character memories, I'd rather see four or five smaller memories. I never have anything so brilliant to send that it would require 100 characters, but I might want to use a bunch of smaller

memories in a contest. Example: For contesting with a normal memory keyer (and paddle), I often load one memory with "WB2WIK;" another one with "QRZ? DE WB2WIK;" another with a full-length (3 x 3) "CQ;" another with a short (1 x 1 or 2 x 2) "CQ;" another with a brief contest exchange like "TU 599 03 DE WB32WIK BK;" another with a slightly different contest exchange like

"The MFJ-451 is the cat's meow (am I aging myself?) and definitely the thing for avid CW ops, or even casual operators who enjoy CW but are tired of banging away on a key."

"CFM TU UR 599 03 DE WB2WIK BK;" another with "CFM (or QSL) TU 73 DE WB2WIK QRZ?" and so forth. I'm used to this format, as most CW contesters are. Lastly, I wish the MFJ-451 didn't consume so much DC current and could be operated from a 9V battery so it would be a true stand-alone unit for portable work. (It does work on 12V, so most portable operations can support it, but this means another DC power cable, another set of connec-

tions, etc.) Note: For home station operation, MFJ does sell a "cube" type power supply, the MFJ-1312B Power Adapter. Many hams will already own such an accessory.

Wrapping Up

The MFJ-451 is the cat's meow (am I aging myself?) and definitely the thing for avid CW ops, or even casual operators who enjoy CW but are tired of banging away on a key. If you're a reasonably good typist, it will give you a perfect "fist" which can be tailored to suit your liking. For the price, I can't believe every ham who ever operated CW won't want one. The MFJ-451 is available from authorized MFJ dealers (which are everywhere) and its suggested retail price is only \$89.95. MFJ's address is P.O. Box 494, Mississippi State, MS 39762. They have two unique customer service programs: (1) If you are interested in any MFJ product, they will send you the owner's manual on request, free of charge; (2) If you buy a product and need technical assistance with it, they have a toll-free help line, which is (800) 647-8324. MFJ has come a long, long way from their start as a little company producing inexpensive ham accessories and I must commend them for growing rapidly and greatly expanding their product line, manufacturing all products in the U.S., and still remaining competitive in this very aggressive marketplace.

A New Look at a Simple VFO/Exciter

Stable tuning with minimal parts.

by Ken Cornell W2IMB

Some 20 years ago many experimenters became interested in the low frequency experimenter's band. To work this band, which ranges from 160 to 190 kHz, many so-called "LOWFERS" used self-excited oscillators to avoid the high cost of low frequency crystals.

As receiving techniques improved, including the use of extremely sharp filters, a stable transmitting frequency became necessary for serious communications.

When the CMOS 4000 series of Binary Ripple Counters (frequency dividers) became available, they permitted us to use high frequency crystals for control and provided divider outputs into the 160 to 190 kHz band. The 4024 and the 4040 were popular ICs using crystals in the 5120 to 6080 kHz range; using the "divide by 32" output would put you into the band. The frequency limitations on these CMOS 4000 series was 6 to 7 MHz.

Some years ago, the high speed 74HC series and 74HCT4000 series became available and these had an operational range up to 50 MHz. The pinout of the 74HC4024 and the 74HC or 74HCT4040 are identical to their CMOS 4020 and 4040 counterparts, with the exception that their operational voltage is 6

volts for 160 to 190 kHz. In this case, any drift in the oscillator would be lessened by 128 times. The end result was an extremely stable signal.

Next came the thought: Why not use this same principle to build a 160, 80 and 40 meter VFO/exciter? By using VFO tuning from 27.2 to 32 MHz, and by using "divide by 16" for 160, divide by 8 for 80 and divide by 4 for 40 meters, a stable VFO emerged.

Construction

I breadboarded several circuits and ended up with the version shown in Figure 1.

I intentionally used easily available disc ceramic capacitors to see how stable the VFO would be. Normally, silver micas and NPOs would be called for in a VFO. However, I was quite pleased with the stability after a short warm-up.

Since the oscillator is operating at a higher

"Due to the light coupling and apparent stable load on the oscillator with the key in either the up or down position, keying is very clean."

volts maximum, making them ideal for operating with a 5 volt regulator such as the 7805.

I got the idea of using a 74HCT4040 with a VFO operating in the 20.48 to 24.32 MHz range and using the "divide by 128" output

Figure 2. Pinout for substituting with the 74HC4024. Note: When the key is used and up, plus bias is applied to Pin 2 which disables the device. When the key is down, Pin 2 is grounded and the chip becomes active. This also applies to the 74HCT4040 at Pin 11.

frequency than the used frequency, it can be left running and that helps the stability.

Due to the light coupling and apparent stable load on the oscillator with the key in either the up or down position, keying is very clean.

The only difficult part is getting the proper tuning range using the slug and tuning capacitor C1. If you don't have access to a frequency counter, I suggest that you take the "divide by 16" output from pin 7 and tune your receiver to the 1500 to 2000 kHz range. Use a good variable capacitor of 50 to 75 pF for C1. Tune the receiver to 1850 kHz and with the tuning capacitor at mid-range, and

adjust the slug in L1 to zero beat. The tuning capacitor should now be able to tune 1700 to 2000 kHz. If the capacitor is too large, you can add a trimmer capacitor in series with same and adjust the tuning to suit.

I suggest that, when you're satisfied with the tuning range, a vernier drive be used for C1. Actually, a fixed capacitor for C1 could be used and the tuning accomplished by using the slug adjustment.

For those who wish to substitute a 74HC4024, the pinout is shown in Figure 2.

As with any VFO, sound construction should be used and the circuit should be enclosed in a shielded cabinet.

Parts Description

C1	See text.
L1	9 turns #22 solid insulated hook-up wire wound on a 5/16" diameter slug tuned form for a 3/4" winding length.
Capacitors	All High "Q" disk types with values as shown.
Resistors	All 1/4 watt.
SW-1	Rotary switch, three positions used.
Key Jack	To suit your key plug.

The ARK 40 QRP Transceiver

Enjoy synthesized tuning in a low-cost monoband rig.

I've said it before many times: "What the world needs is a low-cost synthesized QRP transceiver." Of course, all my friends tell me that's a pipe dream and I'll never see it. Well, it's the '90s—and the folks at S & S Engineering have made my dream come true.

The ARK 40

The ARK 40 is a fully synthesized QRP transceiver running 5 watts on the 40 meter band, a *favorite* QRP band. Band coverage is 7.000 to 7.1999 MHz. Several other bands are also in the works, including 20 and 30 meters. The ARK 40 is a CW *only* transceiver. Full break-in (QSK) keying is used in the ARK 40.

The ARK 40 utilizes a superhet receiver with a bandpass of 600 Hz. The receiver tunes in 100 Hz steps via a push-button thumbwheel. The four digits of the push-button tuning switch represent 100 kHz, 10 kHz, 1 kHz, and 100 Hz respectively.

Sensitivity is rated at 0.3 μ V {10 dB (S + N)/N} with a blocking dynamic range greater than 75 dB. The third order intercept point is a rather impressive $>+10$ dB. The ARK 40 comes to you as a kit, for under \$270. An optional keyer is \$40 and fits inside the ARK 40. The keyer is based on the Curtis 8044 chip. There is enough room inside to install your own keyer board, too.

The ARK 40 comes with a guarantee to work as specified or the manufacturer will fix it for you. If there is a problem caused by a fault of their own, it will cost you only one-way postage to the factory. If it's your fault, they'll fix it for under \$25. The manual gives all the details of the guarantee.

A Look Inside

What makes the ARK 40 stand out among the rest of the QRP monobanders is the synthesized frequency control for both the receiver and the transmitter. By using two phase-locked loops, the expense and complexity of a microprocessor or Direct Digital Synthesizer is avoided.

Signals from the antenna must pass through a low-pass filter and a bandpass filter before reaching the diode mixer. The bandpass filter is approximately 300 kHz wide. The ARK 40 really holds its own during the nighttime SW broadcast station QRM, thanks to the excellent front-end filters. There is no RF gain control.

AGC amplifier. The AGC provides good control of the audio, without a lot of pop and click. There are no clicks or thumps during keying. The AGC action is one of the nicest I've used in a QRP rig in some time. A MC3361 IC is used as a product detector and BFO.

By flipping the audio filter on, you insert a 200 Hz filter into the audio chain. Audio is provided by an LM386 audio amplifier. A sine-wave sidetone generator is injected into the audio line during transmit. The sidetone volume tracks with the front-panel audio gain control. You cannot change the tone of the sidetone.

On the transmitter side, again the synthesizer provides the necessary signals required by the transmitter preamplifier and the MRF-476 final. The final is biased as a Class-C amplifier. To steal a bit of thunder from my computer hacker friends, the transmitter is "what you see is what you get." The transmitter does not "shift" down in frequency when transmitting. If you have dialed up 7.040, you transmit on 7.040.

A relay controls the T/R functions of the ARK 40. This relay supplies the required transmit key voltages and toggles the antenna between receive and transmit.

Photo A. The ARK 40 QRP transceiver.

By generating a 19.0000 to 19.1500 MHz signal on the synthesizer board, and then injecting it to the mixer on the transceiver board, the result is a 12 MHz IF frequency. The IF filter consists of four matched crystal filters. The output of the crystal filter goes to a variable gain amplifier controlled by the

First Impressions

It's true what they say about first impressions. Opening the box of the ARK 40 proved that old saying once again. I'm impressed! The kit contains all the parts you need to fully

Photo B. Front panel wiring on the ARK 40 is kept nice and neat with waxed cable lacing.

assemble the ARK 40. The only thing you have to add is your time and some solder.

There are two main PC boards in the ARK 40, plus one smaller PC board for the thumb-wheel buttons. The synthesizer board and the transceiver board are both the same size. Each PC board comes sealed in its own package with all of its parts. This way, you won't get the parts from the transceiver board mixed up with the parts for the synthesizer board. Both boards are double-sided with plated-through holes. The parts placement guide is also silk-screened on the boards. The boards also have been solder-reflowed, which makes soldering the parts in much easier.

Putting It Together

There are a lot of parts to the ARK 40. If you've never assembled a kit before, you'd better pass on this one. It's not a kit for first-time builders. If you don't know which end of a diode is which, don't try the ARK 40. You should be comfortable working with double-sided PC boards and ICs. You should also be able to remove a part properly should the need arise. Removing parts from a double-sided PC board can be a real pooper!

Time is the one element on your side. If you take your sweet time this can be an enjoyable project. Kits *should* be fun! I had a good time with the ARK 40 on my workbench. In fact, I find it very relaxing to assemble electronic kits. My wife calls it "solder-fume therapy." I assembled my unit during my Memorial Day vacation. The manual states it takes about 16 hours to complete, and I think that's about right. Take your time and you'll enjoy yourself.

Construction begins with the synthesizer board. One of the first things that really

caught my eye was the quality of the parts used in the kit. There are ICs supplied by Harris, National, and Motorola. The same goes for the transistors—they really are marked 2N3904 instead of some off-the-wall surplus part number. All the parts are first-rate and there are no surplus parts used anywhere in the kit. In fact, as I found out later, even the SO-239 antenna connector is supplied by Amphenol; this is no hamfest special.

Because there are so many resistors in the kit, that's where you start construction. Now, either my eyes are getting bad or I'm getting old, but I had one hell of a time telling the value of some resistors from the rest. The violet and the brown on the resistors looked so much alike I ended up getting several in the wrong location. The violet paint must have been rather watery, and it sure looked a lot like brown to me. Take it from me: When building the ARK 40, measure the value of the resistors you're not sure of before soldering them in place.

The kit contained many surprises. The 10k and 1k resistors are packaged separately from the rest of the resistors. This way, you don't have to keep wading through the pile looking for them. The same can be said about the capacitors: All the 0.1 and 0.01 capacitors are packaged separately from the other capacitors. You have no idea how much time that saves in building the ARK 40.

The layout of the PC boards allows you to stuff the board like you're reading a newspaper. Starting from the top left, you go down the board until you hit the bottom, then start back up at the top middle and repeat until all the parts are installed. This way, you won't spend all day long looking for R34 after you install R33. That's because they're right next to each other on the way down the board.

This procedure holds true on both the PC boards, with some slight differences.

On the foil side of the synthesizer board you must install four surface-mount capacitors. They're mighty small, but if you follow the instructions you'll have no trouble soldering them in. S & S Engineering even gives you an extra cap in case you cook one. Don't open the packages holding the surface mount caps until you're ready to install them. There is no way you'll be able to tell one value from another once they are out of their packages. Open only one value at a time, solder them in, then open up the other package.

Coils and Toroids

No one I know of likes to wind coils. So, you can relax with the ARK 40 as all the coils come pre-wound and each type comes packaged in its own little bag. You won't have to count turns of wire on a toroid to determine if it's T4 or L6. In fact, some of the transformers come with the leads pre-formed so you won't get the phasing out of whack. If you do get confused, then you can always go to the oversized drawings which show you how to double-check the coils and install them properly.

Wiring the front and back panels consumes a lot of time with this kit (and with most kits, for that matter). Take your time and you'll have no trouble with the connections. The wiring harness is color coded; it makes connections to the controls and the PC boards easy. Waxed cable lacing cord keeps the wiring from the front and rear panels to the PC boards nice and neat. I cheated here a bit and used nylon cable ties on the rear panel only. The front panel wires I laced up. Cable lacing adds a touch of class to the kit.

The Manual

Any kit worth its salt *must* have a strong manual. S & S Engineering should be very proud of the ARK 40 manual. There are the usual step-by-step instructions, but the manual doesn't go into such fine detail as Heathkit does for installing components like electrolytic capacitors.

The manual features fold-out schematics for both the transceiver and the synthesizer. Oversized PC parts placement guides, as well as foil side only overlays, are included. These overlays come in very handy when installing the surface mount parts.

S & S Engineering printed their manual on quality paper and bound it with a spiral binding so it will lay flat on your workbench. There are plenty of oversized drawings to clarify the mounting of many parts. This is especially useful with the transformers used on the transceiver board. Full-sized photos complement the drawings, so you won't install a wire in the wrong place. I found the photographs especially helpful when soldering the thumb-wheel to its small PC board. If you get this part on backwards (and that would be easy to do) it would be almost impossible to fix. The photographs show exactly how it's installed on the thumbwheel.

But, even with the manual as good as it is,

there were several spots that confused me. Watch carefully the placement of the IC sockets on the transceiver board. The control relay IS mounted in a socket.

Also, I would like to have seen the step-by-step assembly instructions moved from the back of the manual to the appropriate area in the text. For example: The synthesizer board starts on page 3-1, but the check-off list for parts begins on the very last few pages. I had to flip back and forth between the steps up front and the parts check list in the back.

The manual has a very good section on theory of operation on both the synthesizer and the transceiver boards. It's well worth your time to read through these chapters. There's even a chapter on soldering!

There are also several pages on troubleshooting the rig. I would like to have seen an overlay of the PC boards, with transistor voltages listed, to help track down problems.

Alignment and Tune-Up

Although you can align the ARK 40 without fancy test gear, it would be worth your while to have a frequency counter and perhaps a scope, too. A good DVM is required, as is a power supply capable of 2 amps. A wattmeter and a 50 ohm dummy load will be required for tuning the transmitter. Alignment is very simple and straightforward. You simply check for the proper operation of the translation oscillator and the loop oscillator. A counter is best here.

The transceiver PC board requires minor tweaking to get it to operate. There are only two coils to adjust and two small trimmers to tweak. Again, a frequency counter would come in real handy to set the BFO frequency.

Sometime the Dragon Wins

The tune up went smoothly until I reached the transceiver board. The receiver showed no life at all. I could hear my test signal in the speaker, but that was all she wrote. After doing some rough tests, the receiver's mixer seemed to be dead. The audio chain worked and all the inputs from the synthesizer were there. But a call or two to S & S Engineering brought a quick solution to my troubles. Several areas were pinpointed and I went back to the workbench armed with new knowledge.

After a bit more looking I found the problem. It turned out to be a super-thin sliver of copper on the PC board on one of the pads touching the ground foil, shorting out the input to the mixer. The pad is sooooo close to the ground foil that during the board's etching process a tiny piece did not etch away. A sharp knife cut the sliver away from the ground trace. That fixed the receiver and I was golden. Give S & S Engineering an "A" for support.

I notified S & S Engineering about the sliver and they promptly checked all in-house kits for the problem. No others were found, but this shows the attention this company pays to customer service.

On the Air

Operating the ARK 40 is, by design, simple! With only two controls, volume and RIT, you select the frequency you want with the push-buttons, then transmit. It really is that simple. Oh, but it does take some getting used to pushing buttons to change frequency, instead of twisting a knob. I found moving the 1 kHz button up and down the best way to hunt for stations. The buttons are small, and it's easy to go past what you want to tune in. After awhile, tuning with the push-buttons kin-

da grows on you. However, the ARK 40 is a not a contest machine.

This is the only QRP rig in the home-brew club that will allow you to QSY up or down the band with any precision. If you're asked to move up 2 kHz, you can! You can plan a schedule with a buddy back home while you're out in the field and not worry about mistuning the frequency. If you agree on 7.0335, that's exactly where you can go. There is no guessing as to what frequency you're on. It's amazing how stable the receiver is. The ARK 40 does not drift, thanks to the synthesizer. It genuinely is "rock-solid." Of course, some will say even a synthesized rig drifts. That's true, but you would never notice unless you broke out the test gear on the ARK 40.

The MHz digit does not appear on the front panel. So, to "push up" 7.040 MHz, the front panel buttons would read "0400." If QRM is getting rough, then flip on the audio filter. Adjust the RIT to center the signal into the filter, and that's it. The RIT is very smooth and allows you to fine-tune the signal right into the center of the filter. The QSK keying works very well. However, the relay is a tad on the loud side.

Every station I worked commented on the nice CW tone. The ARK 40 keys very well. The sidetone is pleasant to listen to, even after a long-winded CW contact.

The front end keeps most unwanted signals from creeping into the receiver. The matched crystal filter did an effective job on the 40 meter band. Signals seem to pop out of the air. Switching in the audio filter proved useful in pulling stations out of the QRM 90 percent of the time. The ARK 40 sounds so good on receive that I leave it on all the time.

The ARK 40 would be quite happy at home or in a backpack. On receive, it draws 380 mA and my unit produced a fat 5 watts at 1.12 amps. The supply voltage is 13.8 volts. Of course, on a 12.5 volt battery, you'll get a little less RF output. You could run the ARK 40 with one or two 7 amp/hour gel batteries in the woods. A small solar panel is all you would need for long-term use in the field.

With its extruded aluminum case, the ARK 40 is military-grade solid. One would have to try hard to damage it. In fact, had the front and rear controls been waterproofed, I'd take it white water rafting and leave the baggies at home.

So what's the bottom line? The ARK 40 is exactly what the QRP enthusiast (or any ham, for that matter) needs: a simple-to-use monoband rig. S & S Engineering provides you with a rig that produces enough kick to make contacts with less than perfect antennas, while providing the luxury of a fully synthesized transceiver. If you enjoy building kits and like operating with today's technology, you can't go wrong with the ARK 40.

What I would like to see next is a small antenna tuner and switching power supply in the same size case as the ARK 40. A pipe dream? Perhaps, but then who knows? **73**

The ARK 40 is not a kit for beginners.

Amateur Radio and Amateur Solar Astronomy

There's going to be an annular solar eclipse on 10 May 1994. Solar eclipses are spectacular astronomical events in which the moon passes between the earth and sun, temporarily blocking the sun's rays from reaching earth. For a few minutes, the swath of the earth along the eclipse path is bathed in darkness. A total eclipse occurs when the perceived diameter of the moon is such that the sun is totally covered, except for the corona. An annular eclipse, such as the one next May, occurs when the apparent diameter of the moon is smaller than the sun, leaving a ring of light hanging in the sky. Radio propagation is affected by the solar eclipse because, for a brief period of time, the source of energy that causes ionization is interrupted so the average electron (e^-) density changes. The e^- density in the F-layer determines the maximum usable frequency (MUF), while the e^- density in the D-layer determines

the lowest usable frequency (LUF). Figure 1 shows the path of the annular eclipse that will be seen next May . . . note the times are in U.T. (i.e. GMT or "Zulu" time).

What Kind of Ham Experiments Can Be Done?

A review of the amateur radio literature shows that a number of formal experiments and observations have been performed during eclipses over the years. As you will see, there's plenty of real science that you can do with your radio.

Schellenbach (1970) describes observations made on the 40 meter ham band during the eclipse of March 7, 1970. He erected a 1 λ horizontally polarized wire antenna that had four main lobes spaced at 54 degrees from the wire. The antenna was erected at a height of $\lambda/2$ in order to place an elevation lobe at about +30 degrees to optimize D-layer observations. Schellenbach observed a 25 kHz portion of the 40 meter band, working stations and observing signal level changes as the eclipse passed over the land.

Another observation of the 1979

eclipse was reported by Kennedy, et al. (1972). This experiment was performed on the 75 meter amateur band, using CW emissions. Stations 190 km apart arranged to use identical special transmitter keys that would produce a two-second signal on 3,570 kHz every four seconds; the two stations alternating sending signals to each other. The receivers of the stations had the automatic gain control (AGC) function turned off. Output levels were measured with an AC multimeter connected across the speaker connections. As a precaution against ground wave contamination of the data, the antennas of the two stations were oriented end-to-end, so ground-wave signals would be off the nulls of the antennas. The data collected consisted of groups of 10 two-second transmissions, spaced four seconds apart, at intervals of one to two minutes. The 10 pulses in any one group were averaged, and the averages of the groups were compared. A maximum signal change of 17 dB was noted. The two stations took data for a week prior to the eclipse in order to establish a normalized data set.

Menzel (1976) discusses potential observations of the effects of the eclipse of 23 October 1976 on propagation in the upper HF region, i.e. the 10 through 20 meter amateur radio bands. It was noted by Menzel that

during the period of the eclipse there would be a brief return to nighttime propagation conditions for communications paths along, and either side of, the eclipse totality path. This same type of observation is open to short-wave listeners (SWLs) as well as ham operators. The ham operators have a definite advantage, however, because they can schedule contacts with stations in the regions of interest, and don't have to await stations of opportunity to appear. Like Kennedy, Menzel recommends that amateur operators set up schedules for a week prior to the eclipse, at the same time of day, in order to establish a baseline of signal level averages. Otherwise, the measurements made on the day of the eclipse would be less usable.

Johnston and Johnston (1979) performed radiosolar observations of the 26 February 1979 eclipse that crossed the northwestern United States and the western provinces of Canada. They were part of an experiment that used the 75/80 meter band. A set of 12 stations participated, six transmitting in rotation on a two-minute schedule, and six monitoring the others. The transmitting stations sent a five-second identification (call-sign), followed by a two-second quiet period to establish ambient noise level, and then held the key down for 12 seconds to establish signal levels.

Figure 1. Path of the solar eclipse (from a NASA publication).

Receiver S-meter readings were used to establish levels. They observed the effects for three hours, keeping time records in universal coordinate time (UT) through radio station WWV transmissions.

An alternative to using amateur transmitting stations was reported by Smith (1979). He used observations of WWV and several 50 kW AM broadcast band stations to study the propagation effects of the eclipse.

Lewis (1979), in a report preceding the 1979 eclipse, reported on his own literature search. He reported that a Canadian team of scientists at Fort Churchill, MB observed the 20 July 1963 eclipse. In that event, 94 percent of the solar disk was covered. The Canadians used sounding rockets sent to an altitude of 200 km to measure electron density, temperature, ultraviolet and X-radiation. They found that the e- density in the D-layer dropped proportionally to the percentage of the solar disk eclipsed, starting within approximately three minutes. In the E and F1 layers, however, it was found that the e-densities decreased but it was NOT proportional to the percentage of eclipse. The team believes that this nonlinearity is due to the fact that X-radiation is emitted largely by the sun's corona, which is not eclipsed. Such radiation is largely attenuated by the time it reaches the D-layer, so

the effects in that region are more linear.

A group in Urbana, Illinois, USA, used a 2.66 MHz ionosonde instrument to observe a 60 percent eclipse on 10 July 1972. They noted a large decrease in e- at distances of 75-80 km.

the MUF for that day. Estimations of the MUF can be gleaned from the propagation prediction columns in amateur radio and shortwave listener monthly magazines, or from the MiniMUF software.

For eclipse monitoring, use frequencies that are most affected by

burned into their eyesight forever. And if they use a telescope or binoculars to look at the eclipse, then immediate destruction of the eye-sight will occur. If you absolutely MUST look at the eclipse, consult an ophthalmologist for advice on methods and materials that will save your eyesight.

"Observing solar eclipses by eye can be very dangerous! Don't look directly at the eclipse, even briefly. Indirect methods can be found in amateur astronomy books."

Australian researchers observed the eclipse of 23 October 1976 (see also Menzel 1976, above). The Australian observations measured the angle of arrival of 2.5 MHz signals from a station 69 km away. They noticed a "... pronounced oscillating tilt" of the E-layer at 100 km, which lasted some 40 minutes.

Some General RadioSolar Observation Advice

When looking for shortwave fade-outs from SIDs, take advantage of the fact that absorption varies with the square of the frequency (F2), so observations should take place on a frequency as close as practical to

the D- or E-layers of the ionosphere. Lewis recommends using frequencies that are most affected by D-layer, so he prefers frequencies in the 75/80 meter band, or near 5 MHz. He claims that the greatest signal enhancement will occur just before totality reaches the receiver observation site.

WARNING!

Observing solar eclipses by eye can be very dangerous! Don't look directly at the eclipse, even briefly. Indirect methods can be found in amateur astronomy books. Every time an eclipse occurs, it seems that we hear stories of people who look directly at it, only to have the image

"BURN-IN" rack and keyed down for 24 hours non-stop at full power CW. Don't try that with the foreign radios. 4) EVERY SG2000 is then re-checked for alignment and put in the "TORTURE RACK" where they are keyed on and off every 10 seconds for 24 hours. 5) The SG2000 is then re-evaluated and all control functions are verified to ensure that the microprocessor is up to spec. THEN AND ONLY THEN IS THE SG2000 ALLOWED TO LEAVE THE FACTORY.

The bottom line is price. you know how expensive commercial rigs are normally. until DEC 31 we are selling the SG2000 BELOW DEALER COST at only \$1,585.00 each!! That's a \$400.00 savings! We guarantee the best price.

BUY AMERICAN, BETTER PRICE AND QUALITY

The SG2000 HF transceiver is type accepted for commercial and marine service made with traditional U.S. commercial radio quality (and of course it can be used on the ham bands also). While the Japanese radios have 2 final transistors that strain to put out 100 watts on the low bands and only 75-85 watts on ten meters, the SG2000 has 4 large transistors that loaf along at 150 watts on ALL THE BANDS INCLUDING 10 METERS! Some of the SG2000 features are: 1) A control head removable (no special kit necessary) up to 150' away from the rig, perfect for automobiles and boats. Up to 8 heads can be utilized and used as intercoms also. 2) The largest display of any HF transceiver. 3) 644 pre-programmed memories and 100 user programmable memories. 4) operable from -50F (-45C) to 185F (+85C). You want quality right? Here is what EVERY SG2000 must endure before they're shipped from the factory: 1) They're factory aligned. 2) EVERY SG2000 is keyed down at full power (CW 150 Watts) into an open antenna for about 10 seconds, then connected to a shorted antenna and keyed down for an additional 10 seconds. 3) EVERY SG2000 is put in the

To order, send check or money order with \$8.50 for shipping, along with your shipping address (sorry no U.S. Post Office Boxes. UPS will not deliver) and Telephone number to:

Serving The LORD
Since 1987

The SG230 SMART-TUNER is the best HF autotuner at any price, and to promote a product that is made in the USA, we're offering it at the guaranteed best price of only \$449.00!! WHY THE SG230? BECAUSE: When you tune an antenna at it's base you are resonating the antenna, instead of just matching the coax to the radio as with other tuners such as the AT50, etc. The result YOUR SIGNAL GETS OUT MUCH BETTER. The Kenwood AT50, AT450 and other similar tuners can only match 3:1 mismatches (YES only 3:1) so forget matching anything but a fairly decent antenna. The SG230 can match from 0.5 Ohm to 10 kilohm antennas (up to a 200:1 mismatch), so it can easily match random wires, dipoles, rain-gutters, shopping carts, etc. The result MORE POWER.

Getting Started with TCP/IP

[This series of articles explains how to set up a working amateur TCP/IP station. This first installment will sell you on the idea; next month we'll get started with the software itself. The software needed is all available free from many sources (reliable ones will be listed where available). Much of it will be available from the 73 BBS (603/924-9343), though those of you with access to Internet FTP are much better off using it when possible. Some of this first installment is a review of things you may have seen before—for this I apologize. I wanted to be sure that the series was complete.]

So many of you have written—by paper mail and electronically—asking about TCP/IP and ham radio that I have decided I had better write something about how to do it before you start showing up at the door. This series of columns is designed to give you an introduction to TCP/IP over radio, and some how-to-do-it informa-

tion. The BEST way to get started in TCP/IP is to find someone who is already using it, but I'll do my best to explain the ins and outs to the shy and isolated out there.

What Is TCP/IP?

TCP/IP (Transport Control Protocol/Internet Protocol) is a networking scheme developed by ARPA (The DoD's Advanced Research Projects Agency) to make possible the huge collection of computers, cables, routers, and all sorts of other boxes known as the "Internet." The Internet (note the big "I"), is worldwide and carries a mind-boggling amount of data each day. Nearly every university, large company, small technology company, and government agency is connected to the Internet.

Amateur radio is also connected to the Internet, and amateurs worldwide use the resources available there for communications and database services. In fact, as amateurs we have our own network: 44.xx.xx.xx. Any IP address starting with "44" is some sort of amateur station. (We'll look at how addressing works later.) This

44.xx.xx.xx network lets amateurs send mail to (and connect to) stations all over the world. Internet-based services such as the Ottawa converse bridge—which allows real-time chat among hams from all over the world—and the Call Sign server at SUNY Buffalo—containing up-to-date callsign records for all US hams—count on the landline connectivity of the Internet to bring you their services.

Some amateurs will tell you that TCP/IP is not ham radio because it uses landline-based resources. To these self-appointed guardians of the ether I say, "Phooey." (Pretty eloquent, eh?) If you don't like it, don't use it—but leave those of us who want to move into the 20th century alone. Those of you running full-service PBBSs take note: The Internet moves packet traffic—fast! More and more stations acting as gateways from the landline-based Internet to the various radio LANs across the country mean fast, error-free routes for your forwarding, if you know where to tie in.

All of these resources and more, are available through the TCP/IP protocol suite. TCP/IP is a protocol—a set of rules—by which communications of various types can be accomplished. If you are familiar with the idea of "diplomatic protocol"—the set of rules that govern the behavior of government representatives dealing with each other—then you have some idea of what I am talking about. With TCP/IP, stations have a way of contacting each other, establishing a communications channel, and packaging data for transmission.

What About Amateur TCP/IP Over Radio?

In 1989, Phil Karn KA9Q released a program called NOS to the ham community. This program was a first attempt at implementing TCP/IP for use on IBM-PC compatible machines for use over radio. It was—and in many respects still is—an experiment. KA9Q's NOS still provides the *kernel*—a technical term for the heart of an operating system—for the various implementations of TCP/IP hams use today. Since Phil provided the source code to NOS, many ham programmers took the torch and began to develop variants. Today, the resemblance to the original can be remote, but we owe thanks to Phil for his original work—it started a revolution.

Two things make TCP/IP a very powerful networking scheme for amateur radio. One we have already dis-

cussed—the wealth of the Internet. When we use TCP/IP over the air, the use of the landline-based Internet resources is automatic and transparent—like going to a cafe in France and ordering in French. The other is the protocol itself. TCP/IP is based on the idea of services. Each of its various features is a *service*, and is accessed through a *port* or *socket*. This arrangement makes everyone both a client (user) and a server (provider) if they want to be.

TCP/IP Services

There are four services which amateurs will find themselves using most frequently. These provide ways of connecting to other stations and transferring data. These services are the same no matter how you get to them—phone line, Ethernet network, or radio.

Telnet

The telnet service is the workhorse of the TCP/IP environment. Telnet allows a client to start a terminal session at a remote server across the network. In other words, you can login to a remote machine—wherever it happens to be—if it is reachable from your network. In the ham community, telnet is generally reserved for accessing database servers and the like. (See Figure 2 for an example. Telnet was used to reach this Internet resource.)

Telnet can also be used to login to another ham's station in order to use the mailbox there or other resources that might be provided. To continue the call server example, some NOS implementations now support CD-ROM-based callbooks. This could be accessed via telnet.

FTP

The File Transfer Protocol Service allows clients to download or upload files (binary or text) from an FTP server. This is an interactive system and allows the client to change directories, list them, and select file(s) to receive. Batch downloads are supported. If you have tried to download files from an AX.25 station you know it can be frustrating. FTP works like a charm. Recently, a friend downloaded about a quarter of a megabyte of files from my machine—at 1200 baud—in about an hour.

Finger

The finger service allows a client to get information about a particular system or user. The command:

```
*** connected to 128.205.32.2:2000

Figure 1. A typical Sunday afternoon on the converse bridge. It's very late in Europe, or you would see more stations from there. Thanks to the Internet, local converse bridge programs from all over the world are linked together in a big party line. See the text for more.

finger n1ewo@k9iu.ampr.org

will cause the client machine to connect to the finger server at K9IU and make an inquiry about N1EWO. K9IU will then return an informational message about the user N1EWO, providing an informational message whose content is dependent upon K9IU's configuration.

Finger can also be used to provide other sorts of information. For example:

finger weather@iugate.ucs.indiana.edu

returns a weather report for Central and South Central Indiana.

Converse

This service is VERY popular. You can see an example screen from the Ottawa converse bridge in Figure 1. The converse bridge can be a local service, or it can be linked with other bridges over whatever comm link is available. This service is a great deal of fun, and can be truly useful for emergency nets when administered properly. (Those of you who have Internet connections already will find the bridge at 44.135.96.7 3600. You must connect from the amateur net: 44.xx.xx.xx. Connections attempts from any other net will be ignored.)

Yet Another Service . . .

One more service to mention is

called SMTP (Simple Mail Transfer Protocol). Through SMTP, amateur stations can forward their own mail! No more need to login to some remote

Once again we are in France speaking French—these two protocols come from the Internet, and so work perfectly across it and with the

***"If you don't like it, don't use it—
but leave those of us who want to
move into the 20th century alone."***

station and read your mail; SMTP and its cousin POP (Post Office Protocol) will allow every ham to be his own postmaster.

SMTP will automatically forward, through a specified route, any mail addressed to any amateur it knows. It happens transparently, and so easily it seems like magic. With SMTP, you create the mail ON YOUR MACHINE. That's right, you don't login to another machine—you use your own. That is the way things should work.

POP is an alternative to SMTP and makes sense for those who cannot dedicate a machine to running TCP/IP all the time. Like SMTP, POP allows you to use your machine to create messages, and will route them automatically. Unlike SMTP, though, POP calls a post office (another system on your network) and uses a batch technique to send and receive messages. This way, you can check for mail at your post office whenever you start up your system.

machines on it. This means that Internet resources, like list servers which automatically route messages to special interest groups, are available the ham.

OK, OK, I'm Convinced— Now What?

I told you this was a series of articles, and that I would help you get started, so here it is. We will be working with a piece of software called JNOS. This is a variation of KA9Q's NOS, and is available from several sources. The version you will need is 1.08c. I chose this software for several reasons, and there will be those who will argue that it is not the best choice. Here are some of my reasons:

1. It is stable, and still a "live" product. Johann WG7J is still working furiously on new versions, so it will grow as TCP/IP does.

2. It has a decent user interface, but also provides everything that you need to run a full-service PBBS. This

way I can help both the PBBS operator and the average user to get started.

3. I like it, I use it myself.

So, to get started you have to have the software. Those of you who have Internet FTP access will find the program at uscd.edu for anonymous FTP. Those who do not will find it on the 73 BBS, in the packet files area. You will also find the program on ham BBSs around the country. Remember, you want version 1.08c. You will also need a TNC that will operate in KISS mode. If you are unsure of your particular TNC, check the manual. Those of you running BayCom (or equivalent) modems may be able to run JNOS with a special driver. If you want to try, mail me and I'll explain.

Your homework is:

Get version 1.08c of JNOS.

Get a valid TCP/IP address. To do this, contact your local ampr coordinator and ask for one. If you need to find out who your coordinator is, send me mail at either:

Internet:

jsloman@bix.com

or

packet:

N1EWO@N0ARY.#NOCAL.CA.US
A.NOAM

Next month, we'll look at how to set up the software and get that TCP/IP stuff working. 'Til then, 73 de N1EWO.

More on the Amiga

I have been taken to task. I admit it, and I accept the criticism, and I will tell you all about it.

In July, I related the remarks of a ham who told us about his "friend who is a confirmed satellite QSOer. This guy has very elaborate radio equipment, but is using a C-64 for tracking and decoding. Until now, the bit rate has not exceeded 1200 baud, so he has been able to get away with a C-64. Soon, however, things are going to change. The new packet satellites will operate at 9600 baud, and my friend will have to change computers.

"This person will not use a computer for anything other than amateur radio. Therefore, I would like the changeover to be as inexpensive as possible. Is it possible that a Commodore 128 could read and write ASCII at 9600 baud? If this were possible, I believe that he might be able to continue to use his disk drive and printer.

"I feel certain that an Amiga A500 could do it, but I hesitate to recommend a computer which is now an orphan. Please roll this around and let me know what you think. Perhaps there are readers of the column who are facing the same choice."

In my response, I indicated that a PC clone would be a good choice. One of our readers, who wishes his name not be printed, is upset with our "lack of knowledge about Amigas."

"First of all, the Amiga is most definitely NOT an orphan, not even the A500. There are upgraded machines

and an improved operating system. Because of the Amiga operating system's construction, NONE of them have been orphaned. The new AGA (Advanced Graphic Architecture) models are the Amiga 1200, and the Amiga 4000, which Commodore has just spent millions to develop. The older models are the 500, the 2000, and the 3000. Ask the video industry about the Video Toaster . . . they will be surprised to know that the Amiga is an orphan, which is what your column implied. Almost all software that is written for the new Amigas will work on the older models, including terminal programs, ham radio software, graphics software, etc."

He goes on to elaborate on published reports of the "death" of the Amiga which, as with the case of Mark Twain's death, are apparently exaggerated. All in all, he makes a strong case for the Amiga as a capable machine, with a mature multitasking operating system, and a plethora of features built in.

Now, I would like to point out that it was not I who called the Amiga an orphan—I was quoting a reader, much as I quoted our Amiga supporter this month. As to why I have not written more about the Amiga to date, I have heard precious little about it from the readers of this column. Wayne has mentioned the Amiga in his editorials, including the Video Toaster.

I looked back over the last few years of "RTTY Loop" to see just what coverage the Amiga has received. In March 1988 I printed a simple terminal program for the Amiga. In August 1988 a copy of a public domain program for the Amiga was offered for a blank disk

and a mailer, through another reader. November 1989 brought the note that "Amiga users are also on the rise, with Amiga Users Nets on 10 and 75 meters, as well as a number of Amiga users on 20 meter AMTOR." Another user was highlighted in March 1990 with the comment that "hams using Amiga computers seem a bit more versed on the intricacies of this mode." A listing of shareware and commercial RTTY programs for the Amiga was given as well.

So, look'il. I have not ignored the Amiga. For that matter, if you look back in this column, I have not ignored much. How much coverage I give to a given system is directly proportional to how much input from the readers, and even from manufacturers, I get. So, stay tuned, be vocal, and let me hear from you!

Other Questions

Here's a question, for example, from George Lemaster WB5OYP of Falls Church, Virginia. He wonders where one can get a diagram for the Dovelron adjustable filter RTTY demodulator, model MPC-1000T. Somehow, I am sure that some reader, somewhere, can help out.

He also asks about the HAL ST-8000 spectrum display. He'd like to make a scope display which would give an indication of the modulation frequencies and/or FSK type modulation. Once again—anybody?

Finally, here's another request for help, this one from the other side of the globe. Michael Mihailovic VK2OZ in Sydney, Australia, tells of his recent acquisition of a 1984 vintage Kantronics Universal Terminal Unit. He needs help finding a terminal program to run the unit, one with transmit buffers and a type-ahead facility. He wonders if anyone is still using this decade old unit.

He also relates that although he has the operator's manual, he is missing the "Introduction To and Operation of

AMTOR" book that originally came with the Kantronics UTU. He would like to have this book to get onto AMTOR, but is having no luck locating a copy. Kantronics told him, he says, to contact a local Australian agency, which had no idea what he was talking about. If a copy of this book, one would presume even a photocopy, is lying around, this is one amateur who would be very grateful. I would be happy to forward any such material to him, and look forward to hearing from you, out there, who can help.

One of the programs in the RTTY Loop Software Library may well be at least the software answer to Michael's problems, or even yours. The collection continues to grow, with three disks of RTTY/ham software and one of archiving utilities. I try to always include the latest versions of programs available, so even some of the basic disks are subject to updates. A self-addressed, stamped envelope, or an Email note, will get you a listing of all the programs and disks. Each collection pretty well fills a 1.44 Mb disk, and is available for \$2 per disk to be filled, sufficient blank media, and a self-addressed, stamped disk mailer for return to you. As always, Email to me on CompuServe (ppn 75036,2501), Delphi (username MarcWA3AJR), or America Online (screen name MarcWA3AJR) is the quick and easy way to reach me. Postal service hard copy to the above address is fine, too. Just be sure to enclose a self-addressed, stamped envelope if you would like a personal reply. If you would like to put your two cents in, and don't want your name printed, that's fine too, as long as you tell me who you are! I won't print or pay much attention to an anonymous letter, but I will respect your request for privacy if you like. Above all, write me! This column reflects the interests of its readers, and I read those interests through your letters. I look forward to hearing from you.

Foxhunt Fun at the Friendship Games

"An unstable weather pattern is returning to southwestern British Columbia." The weather radio voice coming from my wife April's scanner was discouraging as we awoke on Wednesday, June 23, our first full day in Victoria. Summer showers are the rule rather than the exception on the western Canadian coast, but we were hoping for better conditions for the 1993 Friendship Radiosport Games (FRG-93), just two days away.

Heavy rain had pounded our rental car as we waited for the ferry from the mainland to Vancouver Island the previous day. Such a storm during the FRG-93 radio direction finding contest (the foxhunt) would not be welcome.

To the green-thumbed residents of Victoria, abundant rain makes this provincial capital a perfect place to live. Flowers are everywhere. You see them on lawns, in gardens (called "rockeries") and hanging in uncountable numbers of baskets. We admired them as we made a get-acquainted

trip to Thetis Lake Park, the foxhunt venue. We then drove to the Carey Road campus of Camosun College, where special events station XO7G had been active for several weeks.

Station Manager Al Fast VE7XZ was proud of XO7G, but April and I wanted to visit another of his hamshacks that is just as special. After a short drive we arrived at XO7GRH, in the rehabilitation unit of Gorge Road Hospital. Al introduced us to two of the patients who put this station on the air regularly using voice, CW, and packet.

Like other stations in Victoria, VE7GRH was using the special XO7 prefix made available for the Friendship Games. Al and his friends had installed special adaptive equipment such as oversize switches, voice-read-out rotor controls, and puff-sip keyers to make this station accessible to anyone, even those having no use of their arms and legs (Photo A).

The Mini-Summit

Now it was time to begin last-minute preparations for the Games. We had been invited to the home of Perry (VE7WWP) and Anne Creighton to dine and to finalize rules and procedures for the FRG-93 foxhunt.

Photo A. VE7GRH, the ham station at the Gorge Road Hospital rehabilitation unit, makes it possible for disabled patients to get on the air. This is one of several operating positions.

dures for the FRG-93 foxhunt.

"It's only a couple more places at the table," Perry told us, referring to his current house guests, Evgeny Stavitsky UWØCA, wife Olga, and interpreter Raisa Kucheryavenko UAØCJO. Evgeny is president of the Friendship Amateur Radio Society (FARS) chapter in Khabarovsk, Russia. He led the 15-member Russian delegation to these biennial Games.

Raisa is not only excellent at her translating duties, but is also a superb conversationalist in her own right. Anne insisted that all radio talk be

postponed until after dinner, so we spent two delightful hours getting acquainted and learning about our respective lifestyles.

After dessert, we got down to business. Although Perry had never entered nor witnessed a ham radio foxhunt, he had agreed to organize this event, as Vice President of the hosting FARS Victoria chapter. Evgeny represented the Russians, and I represented Foxhunt Team USA.

We agreed to follow the International Amateur Radio Union (IARU) guidelines for foxhunting championships as

For Repeaters only.

Receiver Voter 4 channel, signal-to-noise

- Improve coverage by adding receivers.
- Expandable to 32 channels by adding additional cards
- Continuous voting
- Available as a card or in a rack system
- Can be used with RF links or Telco lines
- Select/disable switches available for manual override
- External disable inputs
- LED indicators of COR and voted signals
- Remote voted indicators pinned out
- Thousands in service
- Starting at \$370

Remote Base Interface

- Add a Kenwood frequency agile remote base, now to 9 different repeater controllers.
- Connects and controls a maximum of 4 radios or bands
- Supports 16 Kenwood models
- Connects thru the radio's mike jack
- Controls frequency, power, RF power, CTCSS, Shift, etc.
- Expands user function output
- Just plug, program, and play
- \$275

Q Why Pay More For Less?

A Don't! With reliable DAIWA D.C. Power Supplies you won't have to!

More Power, More Features, More Quality - Less Money!

- High Output Capacity - For unit size and weight from Daiwa's super-efficient designs
- Excellent Regulation - With 2.5mV ripple typical; twice as good as most other brands
- Fully Protected - With both state-of-the-art overvoltage and fold-back over current protection circuits
- Adjustable Voltage - Standard on most models, with convenient front-panel voltage control
- Full Metering - Switchable to read voltage or current standard on all adjustable voltage models

With eight models to choose from, in 4 to 40 amp output ranges, you'll find a rugged Daiwa Power Supply to perfectly suit your particular needs!

closely as possible. This 12-page document calls for five "foxes," transmitting in sequence for one minute each. Contestants attempt to locate as many as possible within three hours, carrying a card to mark with the unique punches located at each fox.

Scoring is determined primarily by the number of transmitters found, and secondarily by elapsed time. Contestants are individually timed. They start at five-minute intervals, each coinciding with the start of fox #1 transmissions. This scatters the contestants on the course to minimize "follow the leader" problems.

Successful foxhunters pay attention to the bearings of all transmitters at all times, plotting them on maps provided by the organizers. They also eye their watches, since exceeding the three-hour time limit means disqualification. In other words, it is better to return after 175 minutes with only one fox found than to find all five in 185 minutes.

Each country may field one or more teams of three to five contestants each. Team score is a function of the best three individual scores. Team members are not allowed to help one another on the course. In addition to team medals, corporate sponsor Advanced Electronics Applications provided medals for the top three individual entrants.

IARU rules for foxhunt championships call for separate categories for seniors (males 18 to 40 years), juniors (boys under 18), women (any age—nobody asks!), and "old-timers." Only seniors are required to find all five transmitters in IARU European/

Photo B. Ben Young VE7AJT, the youngest competitor, has just found his first fox and is looking for #2 with one of the Japanese RDF sets.

Photo C. Svetlana Boltchenkova UA0CNE, one of two YLs participating in the foxhunt, leaves the starting corridor. She used a three-element Russian RDF set.

Asian events; others need find only four. Because there was only one junior (Photo B) and two women (Photo C) among the contestants, we agreed

that there would be no special categories in FRG-93. Everyone must attempt to find all five transmitters.

The Russians fielded two teams of

Photo D. At the Sunday demonstration, Evgeny Stavitsky UWØCA shows a blindfolded ham how to get a bearing with a Russian two-element RDF set.

Photo E. Leading Russian team #1 to the foxhunt gold medal were (left to right) Igor Krivosheev UAØCZ, Mikhail Zavarukhin UWØCN, and Alex Savin UAØCDX. They accepted the award at the Saturday night banquet.

four members each. The three-member Canadian team was joined by Yoshiko Yamagami JQ1LCW, the only participant from Japan. Kevin Kelly N6QAB, J. Scott Bovitz N6MI, and Randy Seybold K5TTE competed from the USA.

By the time our rules were finalized, it was getting late. After the traditional toast of Russian vodka to seal the agreement, it was time to go.

Testing...

Perry was admittedly no foxhunt expert, but he had obtained expert assistance. He had called the VicOrienteers, who hold regular outings in

Thetis Lake Park. Alan Philip, one of the organization's leaders, volunteered to help, and brought several other members for timing and Course Marshall duties. No one knows the park better than Alan, who was chief cartographer of the beautiful 1:15000 topographical map supplied to the contestants.

At orienteering events, contestants navigate their way through unfamiliar wooded terrain using only a topo map and compass, looking for previously placed controls (red and white flags) at locations marked on the map. Radiosport foxhunting is similar to orienteering; locations of flags coincide with

the fox transmitters. (But foxes aren't marked on the map, of course!)

Alan had suggested five fox sites, which we tested Thursday. Total distance around the course would be 4-1/2 kilometers. That's not easy, but it's much less than the 12 km courses common in European championships.

Evgeny UWØCA and April WA6OPS stayed at the start/finish point with radio direction finding (RDF) gear as Perry, Alan, and I carried a test transmitter around the course, braving occasional bouts of rain. At each of the five sites, we determined the power and antenna configuration needed to give adequate signal to the

starting corridor.

Southern California T-hunters (N6MI, N6YKE, and AF6O) supplied the five course transmitters and end-point homing beacon. All used N6MBR TBOX boards (see "Homing In" for October 1991) for perfect synchronization.

RDF Equipment: The Scapegoat?

Everyone agreed that the 1991 FRG foxhunt course in Portland, Oregon's Forest Park had been very difficult. Only seven contestants out of 16 found all five transmitters. The Russians felt the RDF sets supplied by FARS-Portland were partly to blame.

CIRCLE 49 ON READER SERVICE CARD

CIRCLE 311 ON READER SERVICE CARD

These dual-antenna units, which work on the time-difference-of-arrival (TDOA) principle, give only direction indication, without strength information.

TDOA sets are susceptible to bearing errors caused by multiple signal paths (multipath). The direct signal competes with reflections from nearby objects, such as hills and trees. When using a TDOA RDF set, it is necessary to keep moving and take bearings very frequently to average out these multipath effects.

The Russians volunteered to provide the competitors' RDF sets for FRG-93. They brought 10 receivers (model Altai-145) from the Barnaul Radio Factory in their country. Altai receiver circuits are cleverly built into the boom of two- or three-element beam of flexible steel tape for safety in the field. There is an AM detector (which also works on FM signals) and a pseudo-BFO that serves as an audible strength indicator for distance estimation.

Altai sets were available for all contestants to use, but some chose to use others. There were a couple of Japanese RDF sets with HB9CV two-element arrays and two of the TDOA units. Russian and Japanese hams have only 144 to 146 MHz on 2 meters, so course transmitters were modified to operate on 145.725 MHz. With no crystal or ceramic filter, the single-conversion Altai receivers are rather broad. But they worked well on this

hunt, except for minor QRM from local packet operations on 145.69 MHz.

Banking Signals Off the Lakeshore

It was our intent that the 1993 foxhunt course be less arduous than 1991's, giving better scores. All foxes were placed near established trails in the southeast corner of the park. Contestants picking the proper 4-1/2 km trail loop would pass close to each one.

Foxhunt Friday brought perfect weather and no malfunctioning of equipment. But to everyone's surprise, scores were poorer than in 1991, overall. Only three competitors found all five foxes. The average was 2.1 foxes found per contestant.

The Russians were clear winners, though they averaged only 3.1 foxes each (Photo E). No doubt their familiarity with European/Asian-style foxhunting and the RDF gear gave them an advantage. But they are also in very good physical condition, when

you consider that their team's average age is 40.

Hunters who didn't do well were probably victims of signal reflections again. This time, however, the bounces came from more distant points. The signal path from fox #1 to the start was unobscured, so most hunters found it. But the direct path from #2 and #3 to #1 was blocked by 200-foot hills.

Sometimes the signal propagated from foxes #2 and #3 by passing over a big lake to the west of the course or a marsh to the northwest, then bouncing off hills on the opposite bank to get back to hunters at the start or at fox #1. In such cases, the classic principle of RDF comes into play: "Your RDF set indicates the direction of incoming signal, which may or may not be in the direction of the fox." Often, it wasn't.

Hunters following reflected signals were drawn into the vast interior of the 2200-acre park. Perry says there is a nude beach somewhere on the

lakeshore. I wonder if any of the contestants discovered it!

Try It Blindfolded

If North American hams are going to hold our own in future European/Asian style foxhunts, we must make them regular events here, to gain experience and to train future champions. To encourage the hams of Victoria, the Russians put on a demonstration Sunday at the FRG hamfest grounds.

To make it more interesting at this flat, treeless campus, attendees were invited to try finding a fox while blindfolded, using only the audible indications of a Russian RDF set to get bearings (Photo D). What fun—maybe this should replace transformer tossing and QLF (left-foot CW sending) contests at our summer hamfests!

Beautiful scenery, friendly competition, exercise, radio talk, and international goodwill—FRG-93 had it all. I could go on about the CW sending and the pile-up contest, the special events station, and the N6MI/K5TTE QRP Field Day in the park, but I want to leave room for plenty of photos to inspire you to add on-foot foxhunting to your club's RDF activities.

The hams of Khabarovsk, Russia, are hosting the next Friendship Radiosport Games in 1995. You're invited. It's not too early to start training. Let's win some medals and help bring the big FARS traveling trophy back to the USA!

NASA Resources

There is such a plethora of books, pamphlets, videos, and other resources out there for teachers to avail themselves of that it sometimes seems like an overwhelming task just to categorize and zero in on where to begin looking for needed classroom materials. With that in mind, I'm dedicating this month's column to helping teachers and instructors of amateur radio to quickly locate some of the resources that NASA has to offer.

With more and more schools participating in SAREX projects, the need for highly motivational lessons and materials about space travel and communications is becoming greater. Ever since my school's SSTV contact with Tony England W0ORE on board the *Challenger* in August 1985, I've always included a unit on space and communications in my ham radio curriculum. The materials are always current and overlap very nicely into science and current events studies. My sixth-, seventh- and eighth-graders really love this portion of the curriculum, and it provides fabulous follow-up and enrichment activities in the classroom.

ment activities in the classroom.

On March 2, 1993, NASA's education staff met with five aerospace education organizations for an overview of each of their programs and a discussion of how NASA can work with them in supporting NASA's Strategic Plan for Education. All five organizations have programs complementary to NASA and all support pre-college education.

1. For eight years now, *The Young Astronaut Council* has targeted students in the K-9 age group. The Y.A.C. supplies space-theme curriculum packages and a teacher's handbook for \$40 annually. Chapters are often funded by community groups such as the PTA, Kiwanis Club, Civil Air Patrol, and Air Force Association. The Council now offers a "distance learning" program using satellite technology to beam space curriculum programming three days a week from their Spokane, Washington, uplink. The Council also recently developed curricula, specifically targeted to reach minority students, through funding from the National Science Foundation. For further information, contact The Young Astronaut Council, 1308 19th St. N.W., Washington DC 20036; (202) 682-1984.

2. *U.S. Space Camp*, a nonprofit educational organization, is open to students in grades 4-12, and to educators

who may participate in graduate or in-service teacher training, workshops, and conferences. The main goal of Space Camp is to motivate students to study mathematics, science, and other high-technology subjects. More than 150,000 students have graduated from Space Camp programs since 1982. Space Camp tuition ranges from \$450 to \$750, excluding air fare. Scholarships are available in three categories: scholastic achievement, ethnic background, and financial need. For further information, contact: U.S. Space Camp, U.S. Space and Rocket Center, P.O. Box 070015, Huntsville AL 35807-7015; (800) 63SPACE.

3. The *U.S. Space Foundation* is a nonprofit educational organization promoting public awareness of America's space programs. It serves as a national resource for research and educational information on all aspects of space. The Foundation, in conjunction with the U.S. Air Force Academy, offers a five-day graduate level course, "Getting Comfortable Teaching with Space." Shorter in-service courses are also available in local school districts on request. Members of the Foundation's "Project First Step" designed an innovative middle school science curriculum using astronauts and other scientists as role models. For more information, contact the Foundation at 2860 S. Circle Dr., Suite 2301, Colorado Springs CO 80906-4184; (719) 576-8000.

4. The *Challenger Center for Space Science Education* is an international network of facilities and programs

founded by the families of the seven crew members of *Challenger* flight 51-L to continue the crew's educational mission. Currently, 14 high-tech space simulators are located in science centers, museums, and school districts across the U.S. and Canada. The simulators fly middle school students through two-hour missions where they learn science and develop problem-solving and communication skills. The *Challenger* Center has developed a wide range of student and teacher programs, which are often led by members of NASA's "Teacher in Space Program." The Center also offers live international teleconferences. For further information, contact The *Challenger* Center for Space Science Education, 1055 North Fairfax St., Suite 100, Alexandria VA 22314; (703) 683-9740.

5. The *Astronaut Memorial Foundation* was established in the aftermath of the *Challenger* accident to honor all 16 astronauts who have lost their lives in the line of duty. The Space Mirror National Monument was established at the Kennedy Space Center by a joint resolution of Congress. In addition, the foundation is creating a Center for Space Education on six acres of land adjacent to the memorial to further enhance NASA's education program. The center will also explore and develop new learning techniques and environments for the future. Plans for group and individual activities run the gamut, including: demonstrations, discussions, conferences, workshops, symposiums, and lectures. The center will also provide films, satellite transmissions, and

Massillon OH 44646

A Low Cost, Low Power Pretzel Transmitter, Good Enough to Eat

This month's project started when I decided to clean up my workbench. Seemed I had all kinds of parts laying about on the bench to build a small transmitter (and a color TV, X-ray machine and so on.) So, with pencil in one hand and a broom in the other, I started working on a schematic while the soldering iron cooked on the workbench. This is a project that just begs to be changed and modified. In fact, I'd be upset if no one modified it for their own use. The schematic is shown in Figure 1.

The project began as a transmitter for 18 MHz but, lacking a proper crystal, the transmitter ended up on 10 MHz instead. Also, I built this project on a single piece of double-sided PC board using the *ugly* construction method. If you've never tried this method before, you're in for a surprise. Normally, you use high-value resistors (1 megohm or higher) as tie points for the various connections. I didn't take this route; I used *sky wiring* instead. In sky wiring, the connections between components just tangle in the air. This does make for a few problems, the biggest of which is having the different connections short out against one another. I fixed this problem by using small pieces of pretzel here and there. I always have a fresh supply of pretzel crumbs on my workbench. And no, I have no idea what the capacitance of a length of pretzel is.

You'll also need at least two sizes of soldering irons. A large, 35 watt iron is needed for soldering to the copper foil. The copper foil is a very good heat sink and a smaller iron (15 watts or less) does not have enough oomph to make a good solder joint on the copper foil. You'll still need a smaller iron, though, to make connections between the individual parts.

To keep the cost down to almost nothing, the antenna connection is simply soldered directly to the output filter. Likewise, the crystal is soldered directly to the VXO capacitor, without a socket. Be careful when soldering to the crystal—too much heat and you'll end up destroying it.

The Circuit

A VXO is used for frequency control. They're simple to build and give you an ideal method of frequency control, without the drift of a VFO. The supply voltage to the oscillator is regulated in two different ways. First, a 78L08 regulator provides a stable +8 volts to the collector of the oscillator's transistor. Second, a red LED is used to supply 1.5 volts of bias to the base of the transistor. A red LED makes a cheap and dirty regulator (and there were plenty laying around my bench).

By adding a small amount of inductance in series with the crystal, we can expand the range of the VXO. The value is not especially critical, so don't get overly concerned with the number of turns to use and on what core. Depending on the crystal, the amount of inductance may need to be changed to get proper VXO action.

Photo A. The junk box rig on 30 meters. Note the pretzel between the buffer and the driver transistor.

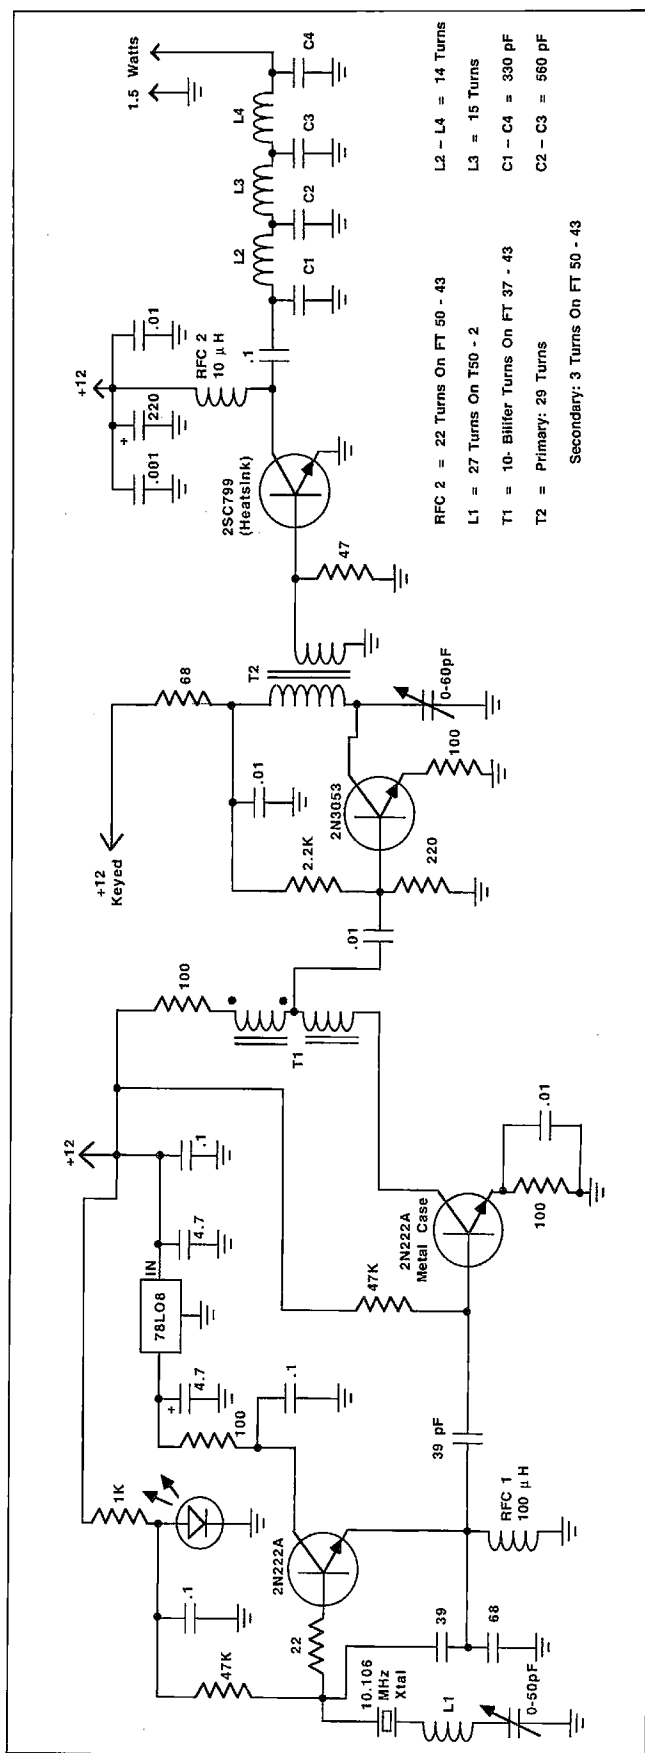

Figure 1. Schematic for the junk box 30 meter pretzel rig.

The main tuning capacitor I have listed as 50 pF on the schematic. In my version, the capacitor I used looks like it may be only 20 or 30 pF. Even with this small value, I'm able to go from 10.115 MHz to 10.122 MHz with a crystal marked 10.116 MHz. That's not too bad, as this range puts me right about in the middle of the action on the 30 meter band. Depending on the value used for your tuning capacitor, crystal and series inductors will determine the frequency swing. Some crystals will bend more than others, giving you greater VXO swings.

The oscillator runs all the time; it is not keyed. The supply voltage of the oscillator must be removed or you'll hear its signal in your receiver. If you plan on using this oscillator for a direct conversion receiver you'll need to keep it running. If you want, a second low-value capacitor may be used to couple some RF into a mixer for your receiver.

Energy from the oscillator is coupled to the buffer via a small capacitor. In my model, I found a 33 pF cap on the bench, so that is what I used. Reducing the value of this capacitor will reduce the amount of RF coupled into the buffer. The smaller the value, the less pulling of the oscillator during keying. To a lesser extent, this will affect the amount of output power, too. Don't go too low or you'll end up with a QRP transmitter. On the other hand, don't use too much capacitance either. It will load down the oscillator and give you no more output at the antenna. Values between 20 and 100 pF should work just fine.

The buffer consists of another 2N2222 transistor. The 2N2222 I used is in the metal-case style. These seem to be a bit harder to kill and I've found you can get a bit more power out of these metal-cased units than the popular plastic jobs. A trans-

former decouples the RF from the collector of the buffer and a small amount is then placed at the base of the driver transistor.

The driver uses a 2N3053 transistor in the TO-5 case. This stage is tuned by the 2-40 pF trimmer on the collector of the driver. The trimmer I used seemed to be a bit too small, so another 37 pF capacitor was soldered in parallel with the trimmer. The driver is the only stage that is keyed. Keying is done by applying +12 volts to the driver. The transmitter keys very well. There are several bypass capacitors on the collector to keep RF out of the VCC line. In most cases a PNP keying transistor would be used here. I could not find one, so I keyed the rig by the "arm-strong" method—I used a clip lead! Figure 2 details a keying transistor and how you would interface it to the project. I did not use a heat sink on this driver transistor, but one wouldn't be a bad idea.

RF from the driver is coupled via the transformer's link turns to the PA transistor. A 47 ohm swamping resistor on the base of the PA transistor

helps stabilize this stage. You'll need to use a heat sink on the PA transistor. The output filter is of a standard design using three toroids. Silver mica capacitors would be my capacitors of choice, but I used ceramic capacitors without any noticeable trouble.

By changing the input impedance of the filter we can get more RF out to the antenna. Normal input impedance is 50 ohms. This was exactly the case in my version. Instead of using the standard value capacitors in the first stage, I changed the input impedance of the filter. I started with 140 pF and, by adding small-value capacitors in parallel, I steadily increased output power. After I got done, I had over 3 watts of clean RF going to the antenna, and a real mess with all those capacitors soldered in parallel! Three watts is about one S-unit over the normal 1.5 watts you'll get. The values shown in the schematic will produce an output power of 1.5 watts. It's up to you to play with the output filter impedance and thus change the output power of the rig.

The transistor used in the PA is

somewhat critical. Because the leads are rather long, it's best not to use a transistor with a lot of gain, especially in the UHF range. That means don't even think about using a 2N3866! I used a junk box version of a 2SC799. A transistor pulled from a junk CB would be a fine choice too.

As I mentioned earlier on, this is a project just begging to be changed and added to. The only points to worry about are the lead lengths on the PA transistor and the driver. Try to keep them as short as possible. This is especially true of the emitter lead of the PA transistor.

Remember, the case of the driver and the PA are connected internally to their collectors. Therefore, they are also connected to the VCC line. Don't allow them to contact the copper foil or you'll end up with fireworks and melted transistor leads.

Have a good time with this project. Even if you don't get it to work, it's great practice in radio theory. If nothing else, find out why something won't work. Learning is always a process of correcting mistakes.

Clear the Pretzels Off the Bench!

One of the reasons I had to clean up my workbench was to start construction of the ARK 40 transceiver. This is really a slick project, especially if you're tired of the usual VXO- or VFO-controlled NE602 transceiver. The ARK 40 will produce a hefty 5 watts output on the 40 meter band. Oh yes, the ARK 40 is a fully synthesized rig on the 40 meter band. It's simple to operate and a joy to use. You can find a complete review of the ARK 40 elsewhere in this issue of 73.

Next month, I'll have some details about computing the values for the output filters. Until then, remember, use wits instead of watts.

73

Figure 2. Schematic for an optional keying transistor and how you would interface it to the project.

NO MORE GUESSING WITH ANTENNA COMPARISON PERFORMANCE. The New "DIGI-FIELD" instrument has an extraordinary frequency response, DC to 12 GHz. "DIGI-FIELD" can be used as a sniffer for 60 cycle noise sources, as well as intensity detector of microwave oven leakage. With visual clear reading, you can make your own calibration. Use for radiation gain/loss measurements, antenna patterns, polarization, adjustments, helps to detect TV, portable phones, car alarm transmitters, etc. Designed to be used with its own telescopic antenna or external antenna with PL 259 connector. Detect or output connector for AM. "DIGI-FIELD" has a 3 1/2 LCD display with (9V) low battery indicator. Available in the normal model "A" or the NEW ultra sensitive model "B".

For only \$119.95 this could be the answer and the solution to your RF problems.

ATV from Mt. Diablo

Just east of the San Francisco Bay Area lies a majestic mountain called Mt. Diablo that rises over 3,800 feet above the surrounding terrain. From the top of Mt. Diablo you can see most of the Bay Area (Berkeley and parts of the East Bay are shielded), as well as an unobstructed view of the Sacramento Valley. On a clear day you can see the snow-capped peaks of the Sierra Nevada range over 100 miles to the east stretching from north of Sacramento nearly down to Fresno. Mt. Diablo would seem to be the ideal site for an ATV repeater.

Don Smith W6NKF certainly thought so! In 1981 he installed his ATV repeater on a site near the top of the mountain. Don's system was a bit unusual since the Bay Area has a unique problem. It turns out that there is a military base near Sacramento that operates an over-the-horizon radar system called Pave Paws. This radar transmits megawatt pulses in the 420-450 MHz range that blanket the Bay Area, particularly the top of Mt. Diablo. Since any input in the 400 MHz band would be constantly wiped out by the radar, Don chose to put the input on the 1200 MHz band with the output on 427.25 MHz. He even worked out an agreement with the Pave Paws operators to keep the 427.25 MHz frequency clear from the radar signals. The repeater's output corresponds exactly with cable-ready channel 58 and allowed many folks to

view the repeater using just a simple antenna and cable-ready VCR or TV set.

The W6CX ATV Repeater

Currently owned and operated by the Mount Diablo Amateur Radio Club, the Mt. Diablo ATV repeater has an input on 1253.25 MHz AM with an output on 427.25 MHz (both vertically polarized). The repeater's antennas are mounted near the top of a 190-foot tower near the mountain peak and provide a 360-degree view of the region. With a range of over 100 miles, the repeater covers most of the San Francisco Bay Area, as well as the Sacramento Valley from north of Sacramento to south of Stockton and into the foothills of the Sierras. There are around 40 active members on the air (and many more who monitor the repeater via cable-ready VCRs). Two of the members reliably access the repeater from over 90 miles away. Occasionally the Black Mountain group will retransmit the Mt. Diablo output through their repeater in the San Jose area so that those in the East Bay can view the activities.

Every Thursday evening at 8 p.m. Pacific time, an ATV net is held on the 147.06 repeater and usually generates a lot of activity. This repeater and the 224.78 repeater are generally used for the ATV talk frequency in the region.

PACIFICON'93

Sponsored by the Mt. Diablo ARC, this year's PACIFICON convention (held October 22-24 at the Concord Hilton hotel) will again feature a live ATV demonstration console (see the photo). The ATV group plans to cover

Photo A. Jim Tittle KC6SOE mans the ATV control console during PACIFICON'92.

featured speakers, special events and highlights of the convention through the use of multiple cameras, videotape and remote feeds. This footage can be seen on the hotel's in-house cable system and will be transmitted through the ATV repeater as well.

One highlight this year will be an ATV balloon launch. Bill Brown WB8ELK and Don Smith W6NKF will be sending up the balloon between 10 a.m. and 11 a.m. on Saturday from the Concord Airport (Buchanan Field), just one mile from the convention. The balloon will feature a live TV camera transmission on 434 MHz, with on-screen telemetry overlay. An on-board GPS receiver will relay the balloon's position to aid in tracking and recovery. In addition, a simplex repeater will operate on 2m (144.34 MHz) and a beacon can be heard on 28.322 MHz. At the peak altitude of 110,000 feet, anyone within 400 miles of the Bay Area should be able to see the balloon's video and work through the re-

peater.

The chase team T-hunt group will be led by Syd Furman W6QWK and anyone with DF gear is invited to join in the chase effort. If all goes well with the Saturday launch, a second flight is tentatively planned for Sunday morning as well.

The Future

A 1200 MHz output for the Mt. Diablo ATV repeater is in the works (in addition to the 427.25 MHz output). Also, plans are being made to eventually establish a microwave linkup with Southern California.

If you'd like to see what's going on in the North Bay area, just drop on by for the Thursday night net and watch the action. With over 50 watts output power (soon to be 100 watts), you should be able to see the repeater with modest equipment (cable-ready VCR/TV and just about any outside antenna) as long as you're line-of-sight to the mountain.

SCARED OF THE CODE?

IT'S A SNAP WITH THE ELEGANTLY SIMPLE MORSE TUTOR ADVANCED EDITION FOR BEGINNERS TO EXPERTS—AND BEYOND

Morse Code teaching software from GGTE is the most popular in the world—and for good reason. You'll learn quickest with the most modern teaching methods—including Farnsworth or standard code, on-screen flashcards, random characters, words and billions of conversations guaranteed to contain every required character every time—in 12 easy lessons.

Sneak through bothersome plateaus in one tenth of a word per minute steps. Or, create your own drills and play them, print them and save them to disk. Import, analyze and convert text to code for additional drills.

Get the software the ARRL sells and uses to create their practice and test tapes. Morse Tutor Advanced Edition is approved for VE exams at all levels. Morse Tutor is great—Morse Tutor Advanced Edition is even better—and it's in user selectable color. Order yours today.

For all MS-DOS computers (including laptops). Available at dealers, thru QST or 73 or send \$29.95 + \$3 S&H (CA residents add 7.75% tax) to:

ARE YOU BUILDING A Packet Network?

Join the latest Packet Radio excitement - building the networks that make it all possible. Using ordinary Packet TNCs with network software installed, you too can expand the existing network, or start your own! ANS has all of the hard-to-find parts that will bring it all together:

The 6-port NETRIX Diode Matrix Board connects TNCs together to form a network switching node, where packets are routed towards their final destination. It uses DIN-9F connectors, is designed to eliminate expensive, unsightly cables, and works with either TheNET or ROSE networking software. \$24.95 as a complete kit, or \$39.95 assembled. Adapters for DR.SI, MFJ or AEA TNCs are only \$2.49 each - specify TNC model.

The WireModem Adapter allows one TNC to connect (via a WireLan Main) to up to 5 other TNCs. Connect switching nodes together to make a Superhub, an inter-network gateway, or to attach a few servers (like a BBS or DX Cluster) directly to the network via wire for superior performance! Only \$2.95 as a kit, or \$4.95 assembled. WireLan Matrix S1, assembled.

To bring it all together, ANS offers TNC to Radio cables (\$9.95) and a Power Supply & TNC cable for the popular TEKK KS-900 link radio (\$24.95).

Please write for more information. To order, send check or MO, add \$3 S/H, NJ address add 6% tax. All orders shipped 2-Day air! Your Satisfaction is Fully Guaranteed.

10 GHz SSB QRP Transceiver

This month I thought I would describe a 10 GHz SSB QRP rig in its simplest form, then later show you how to modify it into a very formidable station. The improvements to the basic SSB converter can be added easily to make it buildable from the components you have. By following the basic layout you should be able to duplicate this rig at various stages of evolution—from the very basic to the more complex 10 GHz SSB station. The IF frequency used in each case is 2 meters.

This design process might look a little awkward but be assured, this rig is quite formidable in operation. Last month we discussed some of the reasons why reduced bandwidth systems are high performers. This month we will discuss this basic 10 GHz SSB system, which delivers high performance yet is constructed from minimum components. Then with this same basic circuit you can add components as you find them. I will attempt to describe several modifications or steps that will guide you in modifying the original unit shown in Photo A. Don't be afraid to make changes—what you build really depends on what you want to spend. The different levels of complexity are offered in an attempt to vary the design to suit your needs.

The main ingredients needed to construct a 10 GHz system include a local oscillator, a Frequency West brick-type amplifier, and the mixer (an orthogonal waveguide-type unit). The RF port of the mixer is connected to a 10 GHz antenna and, with a 2 meter transceiver set to low power, is connected to the IF port. This simple setup will be capable of making narrowband contacts on 10 GHz. See Figure 1 and Photo A, both showing an operating simple system for 10 GHz. This setup will work quite well and is capable of making either narrowband FM or SSB contacts. This, of course, is dependent on the type of 2 meter rig you use for the IF transceiver. My rigs are an ICOM 202, and a Santec LS-202A multimode HT. Both rigs were used. They're both older radios but, they perform quite well. The Santec has been my main radio for SSB operation.

The design of this system is what I prefer to call a "COAXIAL" based system, differing from a "WAVEGUIDE" based system, such as in wideband FM. Components can be added to this system as desired to improve its capa-

bilities. Each component added to the system can increase its complexity and cost. However, each has specific attributes giving system performance improvements that far offset the costs involved. The first improvement to be considered is the RF preamplifier and associated coaxial switch that is needed for a dual role for the amplifier. More on that later.

The preamplifier that we use is a dual-stage amplifier using two MGF-1402 FETs. The amplifier PC board for this amplifier is 3/4" by 1" and constructed on 0.031 Teflon PC board. Figure 2 shows a schematic for this preamp. The source leads are connected to ground on the board with a very short lead length (actually no lead) and upside down. With the case inserted in the hole cut in the PC board (with the FET upside down), the ground foil is soldered directly to this gold metalization of the case, making for almost zero lead length. This is the biggest secret in construction of this PC board amplifier: zero lead length of the source lead, making for minimum inductance in the source path to ground. Please note that some designs require some inductance in the source leads; however, this design does not.

At lower frequencies, FETs give increased gain, and this further increases as frequency is reduced. FETs that have an Ft (frequency total) of 80 GHz or so become unstable at very low frequencies. That's why some source inductance is necessary at low frequencies to help make the design stable. At high microwave frequencies this is undesirable and will make a design function better as an attenuator than as an amplifier. The thing to remember is that the extreme towards minimum is necessary at upper microwave frequencies.

The rest of the construction is basic in that good microwave components

Photo A. A 10 GHz QRP rig. A 20 volt regulator is located on the black heat sink.

are necessary for low loss. That mandates that chip resistors and chip ceramic capacitors be used in the preamplifier. If you wish to design your own amplifier, a program called PUFF is available from CALTECH that will allow you to design your own custom PC board with the FET of your choice.

"Above and Beyond" for May and June 1992 covered PUFF and its applications.

Take, for example, an amplifier which was designed using PUFF with an NEC-04583 FET. This circuit or others could be used in place of the dual-stage amplifier described earlier. Both

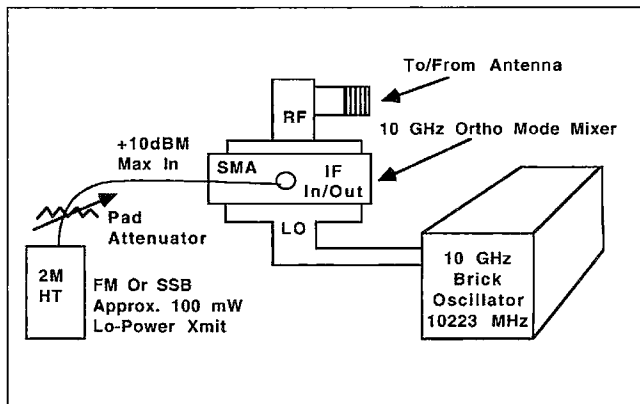

Figure 1. A 10 GHz QRP rig suitable for narrowband FM or SSB.

Photo C. My ICOM-202 SSB 2 meter pre-hand-held radio.

designs require a simple bias supply to function. It can be as simple as a "double A" (AA) flashlight cell connected up to supply negative gate bias current. An additional positive regulator is required as well, for the drain supply. Normally this voltage is near +4 volts. We have built both simple supplies and ones that use ICs to generate the negative voltage. Either will work well.

The bias (negative) is adjusted to give the required drain current for your FET. This can be adjusted for a minimum noise figure or increased for higher current for slightly more power output. Check your FET's specification sheet for exact current requirements. For the MGF 1402 FETs we adjust the first low-noise stage (between 10 and 15 mA) for minimum noise. The second stage is set (to 20 mA) for best gain. Next comes the relay switching. We could live without them and dedicate the amplifier for either receive or transmit. But, in this case I decided to use the same amp for receive and transmit and switch it with relays.

The relay used at 10 GHz must be rated for 10 GHz operation. As such,

the circuitry internal to the coaxial switch resembles a transmission line, providing for low losses at microwave frequencies. Two types of relays can be used: the SPDT (single-pole double-throw) type, or the transfer type. Several SPDT relays would have to be used but only one transfer relay is needed to work in the simplest configuration. I have used each method and they both work well.

For simplicity, the transfer relay is the easiest to use, that is if you can locate one. It is most suitable as only one relay is required, allowing the preamplifier to be used for both receive and transmit amplification. You can usually tell a transfer relay from its standard counterpart by the *four* coaxial connectors on the transfer relay, versus three for a standard SPDT type coaxial relay.

Let's look into the construction of each and see what is going on. In the SPDT type (miniature SMA type relay) there are two sets of contacts, as shown in Figure 4. This relay can best be described as having balanced pole operation, like a teeter-totter. One section makes contact with half of the

common center pin and the other contact (let's call it normally closed). The other section is off balance or down to ground making no contact to any coaxial connector, maximum isolation. When the relay is energized, the normally closed contact toggles and becomes the one that is now grounded or off-balanced and the other section (the normally open contact) is now making connection between the other half of the center contact and the normally open contact. SPDT operation.

The operation in a transfer relay is quite different in some respects in that it has four (coaxial connector) contacts. It has a modification of the teeter-totter operation in that there are four contact bars while the SPDT type has two. The toggle operation occurs between two of these bars diagonally positioned inside the relay. What happens is that the relay makes contact along the top and bottom of the relay, leaving the side bars in the open position. When the relay is activated the top and bottom release their connections and the left and right side bars make connection. See Figure 5 for details on the transfer relay and its schematic switching application.

With either relay system in place, switching an amplifier from receive and transmit is quite easy. It can become complex if and when we add additional components into this switching loop. For a basic SSB unit with switching, this is all you need for an operational SSB 10 GHz narrowband system using 2 meters as an IF. Drive

Figure 4. A SPDT relay.

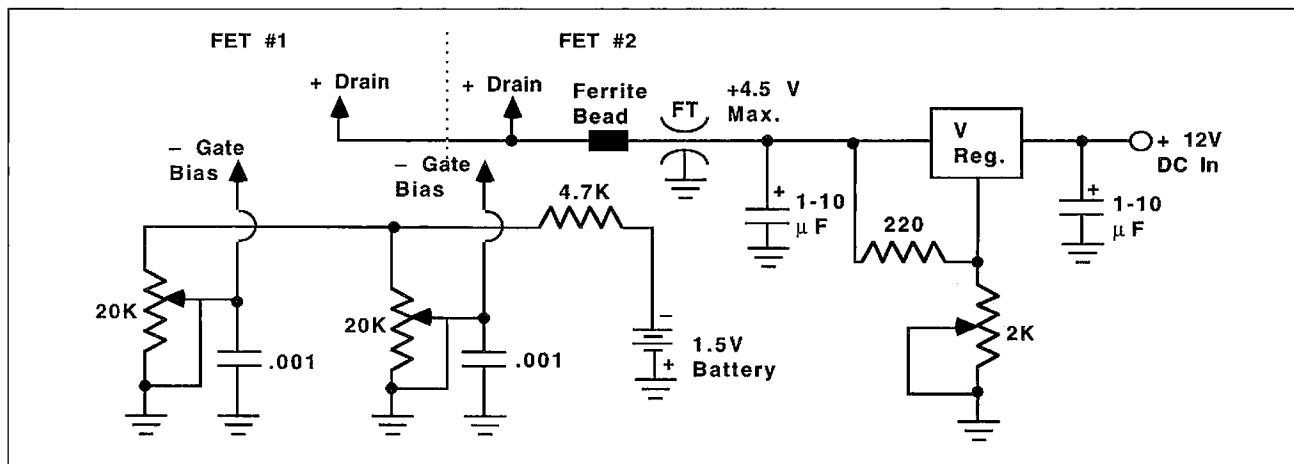

Figure 3. A DC bias supply for the 10 GHz amplifier. The battery should last for a couple of months.

power should be held to +10 dBm maximum to the mixer.

This system, with a 10 GHz FET amplifier (home-brew), can boost output power on transmit to somewhere near the +5 to +8 dBm power level. That's a power output of 4 mW to 7 mW (0.007W). Don't scoff at that power as it is quite capable of driving other higher-power amplifiers, such as traveling wave tubes, to full power of 10 watts or more. These do not need to be added now but can be as time and money allow. The simpler low power rig will work quite well with the lower power level. Additional gain can be quickly realized through passive antenna gains.

Realize that 0.007 watts is real QRP power and can give exceptional operation using SSB. Comparing operation on 10 GHz QRP levels and system gains in respect to lower frequencies such as 2 meters, you can draw comparisons by noting that with lower frequencies antenna gain is markedly reduced. A 30" dish antenna on 10 GHz can exhibit 35 dB gain, making for quite a punch, even when using a QRP rig. That's a lot of gain advantage even when compared to a good 2 meter antenna which can run in the 10 to 15 dB range. You would have quite an antenna farm at 2 meters for similar gain as this small dish at 10 GHz.

That's one factor which makes QRP levels workable with reduced bandwidth SSB microwave operation: very high antenna gain and very low power systems. Comparing even further: At 24 GHz the same approach is used, making more power gain in the antenna than is usually in the amplifier at this level. Most rigs today for 24 GHz are limited to very low QRP levels; that is, before antenna gains. This passive antenna gain is what gives microwave low power level rigs quite a boost in radiated power. This gain in power is the most inexpensive to accomplish in short order. The bad news, at least on 24 GHz, is that the equipment is difficult to obtain even in the land of plenty here in California. If there is inexpensive equipment for 24 GHz then it should be advertised because it would sell.

So much for QRP antennas. The main point is that at a very low QRP level, stations at microwave frequencies are still very effective. The 10 GHz QRP station described above, with or without the preamplifier, is an effective system. Don't let yourself be locked into the design that I presented in the example given. The local oscillator does not have to be a waveguide type of system to mate with an orthogonal type of waveguide mixer. In this case use a waveguide to coaxial transition to accomplish the connection in and out of the mixer. There are many different methods that you can use to make adjustments in system construction and still have a great rig.

Mailbox

Steve Roberts N8VKD of Suffield, Ohio, is looking for others in the Ohio

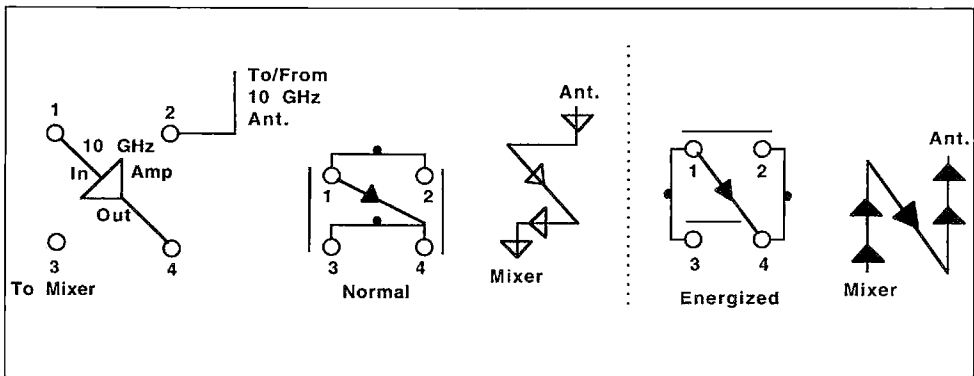

Figure 5. This four-contact transfer relay effectively reverses the amplifier. It is wired with the amplifier in to terminal 1; amplifier out to terminal 4; antenna to terminal 2; mixer out to terminal 3. Normal (not energized) state: contacts 1—2 & 3—4 closed. When energized, the relay opens 1—2 & 3—4 and 1—3 & 2—4 connect.

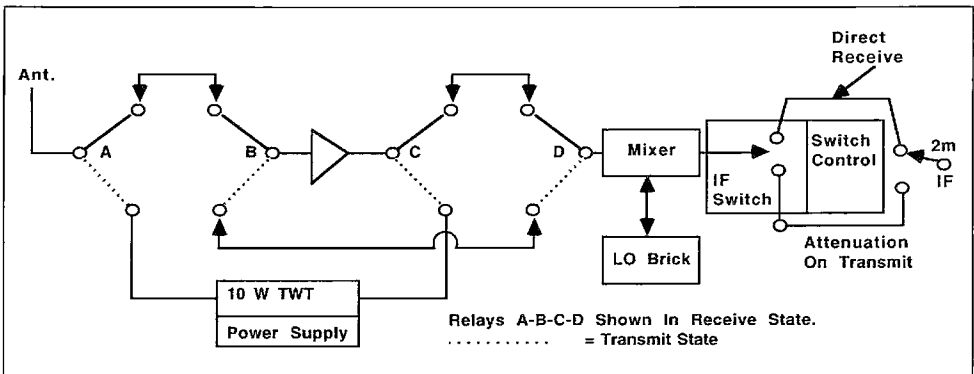

Figure 6. Full implementation of switching with 4 SPDT coax relays, switchable preamp, and 10 watt high power TWT amplifier.

area who are interested in 1.2 GHz and above. He remarked that "if you asked for a Gunn you might get a response like 0.22 or 0.45 caliber." Well, the same mystique abounds here in California. I have difficulty with the knowledge gap, so when you get on to discussing the electron effect in Gunn devices being negative resistance . . . well, you can just imagine the eyes glassing over. It's a hard hill to hoe without some moral support, especially when you know that you are well-founded in scientific fact. Trying to convince someone that negative resistance is a true phenomenon is about as easy as teaching a pig to sing. What we did here was to set up a sign and an operating 10 GHz simple wide-band two-way system at our local ham swap meets and we were able to get quite a response to our pleadings. Later we formed the San Diego Microwave Group.

I think all that is needed is a little prodding and a lot of advertising, similar to the methods we used. Club meetings and such are a good example and I am sure most are looking for a good program to provide for their members. Sure, you won't interest all the members attending, but a good well-rounded information session on your part of the frequency spectrum as it applies to amateur radio in general can come off well.

Raymond N6RE writes that ever

since I published the material on converting the 3.7 GHz LNA amplifiers he has been looking for some to modify. Could we steer him in the right direction? Well, I can only offer some likely sources for you to try. The first is the newspaper—look in the classified ads for satellite antenna installers and also in the Yellow Pages under satellite and TV shops. I made several calls to local shops and most wanted to sell me brand-new units. In bigger shops try to get by the salesman and talk to the repair technician. When I was able to do that I was able to line up some prospects that might prove interesting. One call to a local high profile installer was met with the initial "sell, sell," but when he found out that I wanted older units for amateur applications and not satellite use, he stated that he was licensed also.

I have yet to visit him, and don't expect to be given a box full of units. But, rather, I have found out that for a reasonable (small) dollar amount he would be willing to part with some used units. The price discussed was less than \$15 each, but somewhat higher than the \$5 or so I was accustomed to paying at swap meets. However, his units seemed to be a better bet, as the swap meet prices do not include a guarantee of any kind. It just goes to show that you have to go beyond the normal scrounging attempts and get behind the screens of most

bigger companies and talk to the people doing the work to locate parts. Give it a try.

Richard KBØMR of Aberdeen, South Dakota, writes: "Where can I buy a TWT amplifier similar to the ones you described in the July 1993 issue of 73 Amateur Radio Today?" Well, Richard, they're not the easiest to locate and when amateurs have found them they were not always careful to get matching power supplies and tubes with them. That's the main reason I wrote the article—to inform our readers about what is available in surplus. From time to time I have a spare unit and they have sold for less than \$200 for a working unit. I feel that the price in some surplus outlets is far too high and they don't even guarantee that they will function. I guess they're looking for a customer who is willing to pay the high price for exactly what he wants.

At this moment, I don't have a source for these materials. Components used to come out of Surplus Sales for Collins Electronics in Richardson, Texas. If I locate a source I'll print it; if anyone knows of one please drop me a line.

Well, that's it for this month. As always, I will be glad to answer questions concerning microwave and other amateur related topics. Please send an S.A.S.E. for a quick response.

More Mobile Operation

Last time, we were discussing mobile ham radio installation and operation. Let's continue.

The Real Thing

OK, you got a few bucks together or you got lucky at a hamfest, and you bought yourself a real mobile rig. What can you expect? Well, it sure will work a whole lot better than an HTI. Now you've got anywhere from 10 to 50 watts of power, tremendously greater audio output and, hopefully, a tougher receiver.

Installing a mobile rig is pretty easy, but there are a few things to consider. First of all, you need good, clean DC power at anywhere from 5 to 15 amps. As I mentioned last time, there is no such thing as clean power in a car; it's always loaded with junk. Luckily, mobile rigs, being designed for car use, take that into account and usually have their own internal power filters. Here's a good way to tell: If you have alternator whine, either in transmit or receive, you need an external filter. If not, then

don't worry about it.

If your rig puts out 10 or 15 watts, your power requirements probably aren't that heavy. Most likely, you don't need more than 5 amps. You should be able to get that from the fusebox. A good place to tap in is on the fused side of the line powering your car stereo. Heck, you're not going to be blasting it at high volume and transmitting at the same time, so you're not likely to blow the fuse. And even if you do, there's no big harm done. Just be sure to connect up to the correct side. *Never* run any radio gear (or anything else, for that matter) from an unfused line. The damage you can do to your car just isn't worth it. Of course, if your rig's power cord has its own fuse, then you can hook it up wherever you want. Just keep in mind that any short before the fuse can still cause trouble. In particular, run the wires so that they won't be crimped by the car's brackets or other body parts.

If you have a high-power rig which puts out, say, 40 or 50 watts, you're gonna need some real juice to run it. At 50 watts output, you may need up to 15 amps, and that ain't peanuts, especially because your rig is FM and runs that power *continuously* while you transmit, unlike an SSB HF rig, which only de-

mands high current on voice peaks.

Getting that much current through your car's electrical wiring is asking for trouble. The preferred method is to go directly to the car battery, but that can be tricky. Your car battery can deliver hundreds of amps on demand, and that kind of current is dangerous. Shorting a car battery even for a moment will cause serious sparks and possibly melt the wiring or the battery. The battery may even explode as its internal gasses quickly build up under the heat of its chemical reaction. You can be disfigured, blinded or even killed by an exploding car battery, so please, please play it safe.

How?

First of all, get approved high-current wiring from an autosound or auto parts dealer. Whatever you do, *don't* use coax cable as DC power wiring. Yes, it's shielded and seems to work well, but it is not designed for high DC current, nor is it meant for the temperatures under the hood of a car. The result is that, over time, the inner conductor's plastic jacket will deform and eventually melt through, causing precisely the kind of disastrous short I just discussed above. The risk of an underhood, car-destroying fire is large.

Whatever kind of wire you use, it must be rated to carry the intended current. Also, you must fuse it right at the battery so that shorts anywhere down the line will not cause a disaster. Another fuse right at the radio is a good idea, but that alone will not pro-

tect you if, say, the wire shorts at the firewall or comes in contact with the engine or radiator and melts.

When connecting things to the car battery, be sure to disconnect the battery's negative terminal first so that there can be no return circuit through the car body. That simple precaution can prevent serious injury. Remember, there's enough current there to take your finger off, should it inadvertently connect through a ring you're wearing. It has happened.

Ground?

Obviously, there's no real "ground" on a moving car. But to the circuit, ground is the car body and chassis. Where do you hook the negative lead up? Well, for low-current radios, just about any metal screw in the passenger compartment will do. To check for suitability, use an ohmmeter to be sure the screw is, indeed, connected to the chassis. Especially on late-model cars, many screws are set in plastic, which, obviously, won't do.

In high-current applications, it is best to ground the negative lead to a large screw in the engine compartment, somewhere fairly near the battery. Check the spot where the battery itself connects to ground; what could be better?

Where Does It Go?

In today's small cars, it can be hard to find a good place for your rig. Look for a spot where you can easily operate the controls without interference to your driving. Also, the mike cord has to

reach your mouth without getting tangled in the steering wheel or gearshift lever. And you have to have unobstructed access to the foot pedals. Finally, make sure you don't mount the rig where you will smash into it with a knee or other body part in the event of an accident. If you just can't find such a location, consider buying one of the new rigs which lets you separate the control head from the rest of the radio. The small heads fit just about anywhere.

The Skyhook

Many hams use magnetic-mount antennas because they're easy to remove and hide, and they don't require any installation. They work well, but they do have a tendency to scratch the car's paint. When you put the antenna on, be sure to wipe the mount's bottom off first, because the powerful magnet often picks up little metallic bits and those can really eat your paint away. When the antenna is in the car, be sure to put it somewhere where it can't be seen, and also consider how close you are putting that giant magnet to your stereo, recorded tapes, the rig and other equipment. I keep mine in the back, away from everything.

The coax cable usually exits through the door seal, a window or perhaps the trunk or hatch. The main considerations are that the cable doesn't get crimped (which could result in a transmitter-damaging short) and that rain doesn't get into the car at the entry point. Luckily, most cars have big

enough rubber seals that these problems don't occur.

For permanently mounted antennas, just follow the manufacturer's directions. If you're going with a permanent roof mount, it may be best to let a professional shop do the drilling and mounting. I tried it myself once, and it was very difficult to drill through the roof. Mine eventually worked out fine, but it is possible to have serious leakage problems which result in rust damage.

The Ultimate

Mobile VHF/UHF is plenty of fun, but nothing compares with talking around the world on HF while tooling down the highway. Installing a mobile HF setup is much like installing a high-power VHF/UHF rig, but there are a few extra considerations.

You will need lots of current. Assuming the standard 100 watt rig, figure on 20 amps. Some HF rigs are very tolerant of varying voltage, while others tend to "FM" and pull off frequency or experience other problems if the voltage swings as you talk. So, be sure to use extra-heavy DC wiring and go directly to the battery; forget connecting to the fusebox. All the same guidelines for high-power installation I discussed above apply. With SSB, AM or CW, though, your receiver is amplitude-sensitive, and engine and alternator noise problems will be much worse. You can buy shielded high-current power wiring, and it's probably a good idea. But again, *don't* use coax, no

matter how tempting it may seem. Your rig won't be much use to you if the car burns up.

There are various kinds of mobile HF antennas, but most are designed for bumper mounting. I have had the best results with a standard bumper mount, a whip spring and a guy string. I keep the string tied to the back of my seat and run it out the hatch window to hold the antenna in place. If you have a trunk, you can run it out the top of the trunk after tying it to an internal support.

Running the antenna coax can be a problem. Look at the bottom of your trunk or under your hatch area and you probably will find a few rubber plugs. You should be able to remove one and run the cable through the hole. Be absolutely sure to use some silicone sealer to plug the hole back up, though, or you will have leakage problems. When routing the cable underneath the car, keep it away from the muffler, exhaust pipes and gas tank. Finally, be sure to ground the antenna mount to the car and use some coax sealer to weatherproof the connection. Don't expect to do an HF installation in an hour or two. Usually it takes an entire afternoon.

Well, there's a little more to cover, but I'm running out of room. Before we go, let's look at a letter:

Dear Kaboom,

I'm a 22-year-old sailor in the U.S. Navy. I've enjoyed listening to HF DX since I was 12 years old and hope to

soon have my General Class ham license. I've never really known any ham operators and have lots of questions regarding operating practices, RTTY, packet and such. Is there anybody you could steer me to to get my feet wet? Also, could you tell me which products I should buy to set up a station?

Signed,
Ready To Go

Dear Ready,

I see that you are stationed in Japan. You are lucky to be in the highest per capita ham population in the world. There are over a million hams there and plenty of clubs. Also, they have some serious ham magazines. Unfortunately, you will need to speak Japanese! Lots of U.S. ships have ham facilities because many of the radio operators are hams. Have you checked this out? Perhaps the help you need is right there on the ship! If not, consider getting an English-speaking Japanese friend to show you around or take you to a club meeting. Finally, keep reading 73! As for product recommendations, I'm not in a position to do that. Most of the companies make good gear and the choice is really up to you. The best thing you can do is get your license and get on the air. Once you do, you'll find more opinions and advice than you ever wanted. I hope to hear you on the HF bands!

Until next time, safe and happy mobile from KB1UM.

Notes from FN42

More good stuff for this month including, the FAIRS trip to Bangladesh (S21-land) to train more amateurs there, and a report from Mike Shakhov UA9MI on the DXpedition to Bering Island in 1992.

I am also very happy to report that Lorenzo Gaston DU1CHD/6 has volunteered to become the Ambassador to the Philippines. He enclosed several great articles, but there was not enough room in this issue to print any of them, so look forward to one of them next month.

Since space was a bit short last month, let me be brief so more info can make it across the press. 73, Arnie N1BAC.

Roundup

Bangladesh FAIRS Bangladesh
Trip Report: An international group of FAIRS (Foundation for Amateur

International Radio Service, Inc.) members planned an amateur radio training program in Dhaka, Bangladesh, during early 1993. The training was to help develop a group of amateur radio operators that could lead to the development of a disaster preparedness amateur radio network in Bangladesh. A DXpedition to help provide training by actual amateur operation was planned. The DXpedition operators hoped to make thousands of radio contacts worldwide. These contacts would give great visibility and support for amateur radio and FAIRS in Bangladesh.

The results of two years of planning and almost three weeks on location in Bangladesh exceeded our most optimistic goals. The international team of three Americans (one American traveled from Taiwan), two Ukrainians, and three Russians arrived on schedule with over half a ton of training and radio equipment. A five-day training program in amateur radio for 30 Bangladeshies was

Photo A. QSL of the FAIRS team in Bangladesh.

well-attended. A total of 17 of the 30 participants passed the USA amateur license examinations, which showed there were some highly motivated individuals interested in becoming radio amateur operators. Training for government personnel was provided by Mr. Richard Baldwin, the president of the International Amateur Radio Union (IARU). Mr. Baldwin presented a five-day workshop to about 12 staff members of the Bangladesh Telephone and Telegraph Board (BTTB). His workshop included: the history of ama-

teur and commercial radio, development of international regulations, why amateur radio is good for a country and its citizens, how to develop regulations for governing the use of amateur radio and how to develop amateur radio license procedures. Mr. Baldwin's workshop was independent from FAIRS; however, it was coordinated by FAIRS, the ARRL, and the IARU.

These two training programs made a very significant and positive effect on the interest and awareness of amateur radio in the government,

CONFIRMING QSO WITH	DATE DAY MONTH YEAR	UTC	MHZ	RST	MODE 2-WAY

After covering the distance of nearly 4,000 miles with baggage weighing about 2,000 pounds, we reached Bering Island, a Pacific Ocean island which has a land area of about 600 square miles. It's coordinates are 55 N. and 166 E., IOTA nr AS-39. The expedition was organized by the Western Siberia DX Club with support from the Russian Geographic magazine "Vitus". The radio shack was situated 100 yards from the ocean shore in a little house which was kindly placed at our disposal by the island meteorological station. Having started to operate, we expected to have a great time for ten days. But then something terrible happened...

Photo B. QSL of the DXpedition to Bering Island.

N.G.O., and private sector.

The FAIRS team was fortunate to meet with many officials of the government ministry for telephone and telecommunications in favorable discussions supporting amateur radio. Five Bangladesh amateur radio licenses were issued to our team by BTB. More than 25,000 radio contacts with amateurs worldwide were made with the three radio stations brought from the USA, Ukraine, and Russia. The FAIRS radio DXpedition was a tremendous success and as a result thousands of radio amateurs

and others around the world will be aware of the new interest in amateur radio in Bangladesh.

The international FAIRS team included: David Larsen KK4WW/UB5WUS/S21ZJ, Executive Director, FAIRS; Gaynell Larsen KD4GMV/UB5WMV/S21ZH, Vice Director, FAIRS; Victor Goncharky UB5WE/KC1VF/S21ZM, FAIRS European Operations Director; Helen Goncharky RB5WA/KB0KNC/S21ZM (2nd op), FAIRS Europe Secretary; Yuri Katyutin UA4LCQ/KD4STR/S21ZL, Director of Opera-

tions, FAIRS Russia; Larry Vogt BV/N4VA/S21ZK, FAIRS Training Director, ITU Region 3; Serge Tarasov UA4LLQ/KD4QAU/S21ZL (2nd op), FAIRS member Russia; and Vyacheslav Sergeev, CIS Team Sponsor.

For further information about this trip, future trips, or about FAIRS, contact David Larsen, Executive Director, FAIRS, PO Box 341, Floyd VA 24091, USA; (703) 231-6478; (703) 382-9099; Fax: (703) 382-2935; Internet: david.larsen@fairs.org.

[There was much more of their report, but space was not available to print it all.—Arnie]

Russia HELLO FROM BERING ISLAND! From August 25 to September 7, 1992, four members of the West Siberian DX Club operated a station located on Bering Island, coordinates 55 North and 166 East, IOTA AS-39. The expedition was organized with some support and direct participation of the Russian geographic magazine *Vitus*.

The expedition was devoted to the 250th anniversary of the discovery of the Commodore Islands by Russian explorers under the leadership of Captain Vitus Bering. The radio DXpedition was comprised of

four radio amateurs from the city of Omsk, oblast 146: Valery Matushin UA9NN, chief of the WSDXC; Alexander Ernst UA9MR; Igor Suprunov UA9MFW; and Mike Shakirov UA9MI.

After traveling a distance of 4,000 miles with about 500 kg. of baggage, we reached the Pacific Ocean island of Bering. The island is about 600 square miles of land area and has a population of 1,500 people. Our license gave us permission to operate as 4K4NN and 4K4West Siberia. We were going to operate with the latter call in the All Asian Contest.

The radio shack was situated 100 yards from the shoreline on the first floor of a small house which was kindly placed at our disposal by the island meteorological station. Our equipment included Yaesu FT757GX and ICOM 701 transceivers, a 1 kW amplifier, and an MFJ-949D tuner. Due to a good choice of a clearing with green grass, and the sunny weather, we quickly put up the antennas, a three-element yagi on the 15 and 20 meter bands, a full-size ground plane on 40 meters, and a longwire for the other bands.

We operated 24 hours a day with the best propagation to the USA

How To Get Started In Packet Radio

Enter the exciting world of packet radio today with *How To Get Started In Packet Radio*. Dave Ingram, K4TWJ, wrote this beginner's guide to packet radio in an

easy-to-understand manner. It starts with a non-technical description of packet radio, followed by chapters that include getting started, setting up your station, networks, BBSs, portable and high-frequency operation and even a *Packet Radio Equipment Survey*. There's also an appendix that includes circuits for interfacing equipment. Join the most exciting and rapidly growing area of ham radio today! Order your copy of *How To Get Started In Packet Radio* book for only \$9.95! (plus \$2.00 S&H).

and Japan and some good openings to the South Pacific. The propagation to Europe was fair in the morning and evening. Most signals to all locations were only about S3 to S5! The best propagation was at the end of August, but beginning in September the propagation abruptly deteriorated. Unfortunately, we failed to operate on the 10 and 12 meter bands while propagation was good in August. During that time, we worked on the 30, 40, and 80 meter bands.

On the 5th of September, hurricane force winds hit the island! The winds gusted up to 80 miles per hour, and the temperature dropped to 0 degrees C, or about 30 degrees F. The wind raged for two days and destroyed all of our antennas and our plans for future operations! Luckily, the building where our shack was located did not suffer any damage.

It must be said that the author of these lines, as well as the other members of the DXpedition, were shocked with the rage of the hurricane. It was the first time that we had witnessed this natural phenomenon. Because of the hurricane, we were not able to carry out our plans to take part in the All Asian Contest or launch a balloon with a longwire for the 160 meter band. We had also planned to operate from Medny Island (Cooper), a smaller island in this group.

On Tuesday, the 8th of September, we left our troubles and the debris of our antennas on the island and flew in a small airplane back to the continent. It took us 48 hours to

get back to our homes in Omsk, Russia.

We made over 10,000 QSOs during the DXpedition, with 140 DXCC countries on SSB and CW, including the WARC bands. The following totals will tell the story: 80m—504; 40m—2061; 30m—463; 20m 5063; 17m—431; and 15m—1557.

In conclusion, we wish to thank all of the hams who worked us, and we are especially obliged to our QSL managers, Ken KC4UG and Walter DK8FS for spiritual and material support. We also want to thank MFJ Enterprises in Mississippi for the 1278 multimode controllers, which helped us to make plans for the DXpedition.

[Many thanks to Ken Carpenter KC4UG, PO Box 586, Vernon AL 35592, for this report from Mike and group. Ken reports that he has operated Mike's home station in Omsk and it is awesome, consisting of a TS-400, 2 kW amp, and seven elements on 15 and five elements on 20 meters. The antennas are on a tower on his 10-story apartment building. Ken would be glad to help arrange for a UA9M callsign for any who would like to travel in that direction. Mike's info is Mike Shkirov UA9MI, PO Box 2056, Omsk 644119, Russia.—Amie]

Techeat, Israel's first amateur radio satellite project, continues full steam ahead at the Technion Technical University in Haifa. Launch of the bird, which will feature an orbiting packet radio mailbox for hams, is slated for 1995.

Its BBS software has already been written, and it should soon be

in operation (terrestrially) from Bet Miller, home of the 4X4HF club, in Haifa. This will give people a taste of what it will be like connecting to the bird and will no doubt whet their appetites for the real thing. The simulated satellite BBS will be on AFSK FM, at first on 1200 baud and later switching to the faster 9600 baud rate. As with the Mode J type of operation slated for the satellite, those wishing to connect to the BBS will transmit on 2 metres and receive on 70 centimetres. The computer for this project has been donated by the Haifa Rotary Club. In a future report, we hope to have a more detailed re-

port from some of the hams involved in the project.

With the sword of Damocles hanging over the wholeness of the 70 centimetre band, hams are beginning to wake up. In the last few weeks, three packet BBSs have been hastily set up on the band: on 430.400 MHz, a port of 4X4HF in Haifa; 433.450, 4X1RU in Herzliya (both of these part of the 4XNet and World-Wide Packet system) and 4X6SL in Tel-Aviv on 433.625, a private BBS on the air every evening, chock full of files and public domain software. All of these BBSs are working on standard 1200 baud.

By the time you read this, there should be a new UHF FM repeater activated in Jerusalem, and one is planned for Beersheva as well. What's in store for 70 centimetres in Israel? Is its fate sealed? To be continued...

[More next month when space permits.—Amie]

REPUBLIC OF KOREA

Byong-Joo Cho HL5AP
Room 401 CQ Building
157-7 Kwangan-2Dong, Nam-Ku
Pusan 608-102
Korea

Korea was proud to announce that EXPO '93, the Taejon International Exposition, will be held in Taedok Science Town, Taejon City, from August 7 to November 7, 1993. The theme is "The Challenge of a New Road to Developing" with a sub-theme of "Traditional and Modern Technologies for the Developing World, toward improved use and re-

cycling of resources."

The Taejon International Exposition and the Korean Amateur Radio League (KARL) are co-sponsoring an award, appropriately named the "EXPO '93 Award," that is available to all amateur radio stations and SWLs all over the world. Further information can be received from, and applications sent to: Award Desk, Korean Amateur Radio League, C.P.O. Box 162, Seoul, 100-601, Korea.

"With the sword of Damocles hanging over the wholeness of the 70 centimetre band, hams are beginning to wake up."

There will also be a Special Event Station set up at the EXPO. The callsign will be 6K93EXP during the EXPO '93 run. I am happy to report that I will spend some time at the operator's position and will be very happy to say "Hi" to my many friends.

RUSSIA

Gennady Kolmakov UA9MA
PO Box 341
Omsk-99
Russia

There are serious troubles looming on the horizon for the amateurs of the former USSR. Obsessed with "market economy," people in charge

of Amateur Radio Service on the government level have imposed (or will impose very soon) substantial fees for the privilege of operating on the air.

A First Class license (equivalent of the U.S. Extra) will cost a ham 120 rubles per annum. To enter any contests, one would fork over 240 rubles per year in addition to the above. It won't matter if you run 100 watts or 10 kW. Special calls call for yet more money. In U.S. currency

this doesn't look like much (\$1 = 500 rubles), but it sets a dangerous pattern—pay for what once was free and expect an increase any time. The opinions of ham ops were never requested, it seems.

In addition, getting contest certificates via the bureau would cost five rubles, receiving a single card via the bureau now costs 50 kopecks, sending a single card abroad via the bureau would cost two rubles 15 kopecks.

An airmail letter from Russia to anywhere in the world now costs 75 rubles. Since the majority of hams can't afford to send airmail letters (the average salary now stands at 3,000-4,000 rubles per month) in

quantity, and because the foreign mail isn't getting through to Russia, those U-cards will become very rare indeed very soon. Moscow hams report piles upon piles of incoming QSLs at Box 88 that don't and won't get processed. The bureau is broke, can't pay employees and its own mailing expenses. Again, hold onto your CIS cards, don't mail them over here until the situation is resolved.

On a related subject, January 1993 was set as a time frame for the changeover of current amateur call-sign allocations to a new system. 95% of all Ukrainian calls will change and a substantial amount of Russian calls, if the new system is implemented. Other republics will see a full 100% change of existing calls. As was announced earlier, the new allocations were assigned without any consultations with hams, thus the amateur community of the former USSR republics is in a state of turmoil. Nobody knows what will take place, when and how. Letters were sent to the ITU, trying to stop the new assignments. Government offices responsible for communications were petitioned without any obvious results. There is talk about having hams retain the present call-sign system, while commercial and utility calls would be converted. At this time, it is all pure speculation and no decisions on this explosive topic were rendered. There would be no special calls assigned within the CIS for 1993. I was told, pending the outcome of the above.

As always, I will provide more details as they become available. 73 de UA9MA.

HAM HELP

Number 30 on your Feedback card

We are happy to provide Ham Help listings free on a space available basis. To make our job easier and to ensure that your listing is correct, please type or print your request clearly, double spaced, on a full 8 1/2" x 11" sheet of paper. Use upper- and lower-case letters where appropriate. Also, print numbers carefully—a 1, for example, can be misread as the letters l or i, or even the number 7. You may also upload a listing as E-mail to Sysop to the 73 BBS, (603) 924-9343, (8 data bits, 0 parity, 1 stop bit, 2400 baud), on Special Events Message Area #11. Specifically mention that your message is for publication. Please remember to acknowledge responses to your requests. Thank you for your cooperation.

Needed: Information on Tecraft Criterion series NU-VERTER Model 144, IF Freq. 14-18 mc. Thanks. *Art Coulombe W7HGK, 21 Yakima St., Walla Walla WA 99362.*

I'd like to exchange schematics/project ideas with other homebrewers. Please send a list of your projects, and I'll send a list of mine; or if you don't have a list of your own, please send an SASE and I'll send you a list of my projects (some have been published). *Klaus Spies, Lock Box 48185, Niles IL 60714-0185.*

Wanted: Knight R100A Receiver. Thank you. *Walter J. Stanis, Box 231347, San Diego CA 92194.*

I need manual/assembly instructions/schematic for VHF Engineering "Synthesizer II." This was how you made a rig programmable in the '70s. Will pay reasonable copy costs. *Joel S. Look W1KCR, 35 Goff Ave. Apt. 507, Pawtucket RI 02860.*

Wanted: Source info of antenna materials, such as tubing of various lengths and diameters; various types of element insulators; whip antenna rod material (such as one would find in commercially available HAM units). Ham is involved in the designing, experimenting and building of antennas. *Ron Zemljak N7LDQ, 140 Maude 'S' Canyon, Butte MT 59701.*

SPECIAL EVENTS

Number 24 on your Feedback card

Ham Doings Around the World

Listings are free of charge as space permits. Please send us your Special Event two months in advance of the issue you want it to appear in. For example, if you want it to appear in the January issue, we should receive it by October 31. Provide a clear, concise summary of the essential details about your Special Event. Check **Special Events File Area #11** on our BBS (603-924-9343). For listings that were too late to get into publication.

OCT 2-3

New from England—

THE MICROREADER MkII DECODES CW FOR YOU!

RTTY, AMTOR and more! Especially helpful for new Hams and SWLs. Send for FREE brochure right away.

The ERA MkII Microreader, Britain's most popular self-contained decoder, has a unique ability to copy poorly sent CW. It's designed to work with almost any receiver. Just plug the Microreader into the headphone or speaker jack of your receiving equipment and you're ready to go. Microreader's ability to copy poorly sent CW under noisy conditions is unique. The built-in CW tutor is simply outstanding for learning to send and receive. In addition, the MkII gives you hours of pleasure reading decoded RTTY and AMTOR.

- Supply Requirements: 12V to 16V DC.
- Display: 16 character right to left scrolling.
- CW tutor allows you to plug in your key and see what you're sending is really like.
- RS232 output port sends decoded text to serial printers and computers. No interface needed.

NEVER SAY DIE

Continued from page 4

What do you talk about when you make a contact? Are you actually talking about anything, or is your mike fright so bad that all you can do is list the model numbers of your equipment and antennas, mention the weather, spell out your name and turn it back? Go get a life! For heaven's sake do something you can talk about! I don't give a damn what rig you're using. I don't care what brand of antenna you were able to afford. I don't care that it's raining. I want to know something about you.

No, I don't want to sit and listen while you rant about something you're emotionally disturbed about. That's no fun. But I would be interested in any interesting ham adventures you've had. If you've read my editorials for any time you know about everything I'm interested in. I'm into all kinds of hobbies and several active sports. I read a ton of books and magazines and will be most interested in anything you've read and found interesting that I might have missed. I love getting letters from readers giving me leads on books I'll enjoy reading or music I might enjoy hearing.

What I don't need is to get on a repeater where there's some resident retired old codger who rambles on endlessly about nothing, month after month. You've got one of those around, right? Heck, I'd even get

bored listening to someone like this year's Ham O' The Year award winner and his obsession with me and my admittedly adventurous life. These old guys must have something that interests them other than ham radio. Or, if they have never done anything in their lives outside of hamming, isn't there something interesting they've done in amateur radio?

I've told you how much fun I had hamming from the demilitarized zone between North and South Korea as HL9WG, right? Or getting on the air as 7P8CA from Lesotho. You can surely get a good QSO going by asking if they've read what that arrogant, egotistical asshole Wayne Green wrote this month. Well, don't use those exact words. They might offend some Nervous Nelly listening in. We've enough garbage-mouth stuff going on without you contributing to the mess. The language you use on the air is a clear announcement of your class in society. After a few words we know right where you fit in, so if we hear you using bad language and fractured grammar, we wonder why you aren't on CB where you belong. How did an ignorant slob like that get a ham ticket? Maybe that code test isn't enough of an obstacle.

I suppose I'm preaching to the choir. The chaps who need my advice the most wouldn't read 73 if their life depended on it. Not with all that ARRL bashing they think I do. Of course they've never read 73, so they're going by word of mouth about my writing.

I keep trying to get you to break loose and go on a DXpedition. That'll give you something interesting to talk about for years. You might even get in to slow-scan just so you can show your slides. And I'll love watching 'em. Yes, I know, you can't afford anything like that. Unless you're really into poverty as a way of life, there are plenty of easy DXpedition places to visit and have the time of your life.

Heck, you can drive to Nova Scotia and take a boat or plane to St. Pierre for a surprisingly low bucks. It's a bargain place to visit and they love visiting hams. I'm frugal, and I've never cared much about making money, and hate spending it. At least on myself. I've spent millions helping other people start businesses.

The Caribbean is another bargain place to visit and there are a dozen or so fairly rare spots you can activate. You can get there in a day, so you don't even need to have more than a week off to have a ball. Try it. Then write and thank me for pushing you. Also, let's see an article for 73 or *Radio Fun*.

What are you into that you can talk about? Bicycling? Kayaking? Scuba? Roller blades? Ultra-lights? Para-planing? Rallying? Sky diving? Ballooning? Gliding? Model planes? You're not a one-dimensional person, are you?

Many years ago I suggested we set up some net times and frequencies for hams with similar interests to meet

and talk. Nothing came of it. One problem with nets is that once you have more than two or three stations involved there's a reluctance to say much. The result is that a bunch of ops check into the net and say hello. And that's about it.

There's a weekly submariners net. I called in a couple times. Now, I've got hours of interesting submarine yams to tell, but I never found an opportunity. So I stopped checking in. The net was on 20m, which meant that half of the checkins couldn't hear the other half, which puts a real chill on talking for any length of time. Interest groups should stick to 80m and maybe 160m, where everyone can hear everyone else. Or perhaps 2m via a repeater.

Always try to be your very best at anything you do. So when it comes to hamming, invest what it takes to make you the most interesting ham on the band to talk with. Work hard at it. Tape yourself and take the time to critique it. Be upbeat. No one likes a sour apple, so griping and negativity will have people avoiding you the next time around. I get letters from hams who obviously are devoting their lives to making as many people unhappy as possible. I sure hate when I run into 'em on the air.

That last QSO... was that the very best you're able to do?

Trivia

One of the ham rags made a great big deal out of a TV production outfit

that rented some 2m HTs instead of commercial frequency HTs from a commercial communications firm. They innocently used 'em. We'll eventually hear whether the rental company got conned when they bought the HTs or if they knew the frequencies were wrong. But shame on blaming the TV production company . . . another Chicken-Little hysterical reaction.

The ARRL vs. gays score seems to be gays 2, ARRL 0. The League backed down on their refusal to continue publishing classified ads soliciting gay hams to join their movement. Now the gays, not satisfied with just winning, are suing for damages. Har-de-har . . . another item for the "Only In America" record book.

Getting Involved

As a communications and technology expert, you should consider becoming involved in local activities. Business people, educators, politicians, and even your local bureaucrats are beginning to recognize that the information age is dawning on America and they'd better damn well get aboard or they're going to be left behind by the rest of the world.

They've been hearing John Scully, now the chairman of Apple, talk about the information highway of the future, while all most people can see right now is more like a cow path. They see that Singapore is setting about installing fiber optic cable into every home and business in the country. In

France, every home has an on-line computer connected to a national data base.

We've been seeing the changes in our own lives as our ham repeaters have turned into cellular telephone systems. We've seen facsimile explode. Those of you who are awake have seen pocket communicators which handle voice and fax. We've seen national paging systems grow.

As a radio amateur, naturally you're expected by your neighbors to be an expert on communications and technology. Thus, when a few local politicians start getting concerned over the general ignorance of these highly technical matters, naturally they're going to turn to you for advice on how to get your county or state more tuned in with the future. Business people must find out how to take advantage of this technology and not be left behind by other parts of the country . . . or other countries. Schools must start turning out workers familiar with information and communications technology.

How prepared are you for this? How much do you know about what's available right now in technology, much less what's developing? Are you still sitting there, happily clacking away with your beloved old hand key, while the world is going to digital voice communications? And probably using spread-spectrum?

While we're communicating at 5 wpm by code, the world is moving to digital communications because digital

radio provides about three times the coverage with a hundredth of the power. Further, it's easy to put 10 to 20 people all on one channel without mutual interference. Heck, they can even talk with each other, just as we do on the telephone. And, by using satellites in the link, the 10 to 20 people can be in 10 to 20 different countries. Yes, we could do all this via amateur radio, if we had anyone pioneering new technologies in our fraternity.

Alas, all too many hams prefer to remain fat, dumb, and happy. Ooops, make that fat, dumb, and unhappy . . . because they're forever grousing and kvetching on the air about things. Those damned no-coders. The rotten CBers. Lousy phone patches. Stinking pile-ups. Miserable contests crapping up the bands. That fathead and his little band of degenerates puking their venom on 14.313. The endless self-promotion broadcasts by an internationally famous ego case on 14.275. And worst, that awful Wayne Green! How can someone who sounds so nice on the air write such abrasive baloney?

I digress. My aim was to stir some deep feelings of guilt for the way you've wasted your ham life on inconsequential. Well-deserved guilt. You've been skimming the cream and not paying your dues. That's pure American . . . get the most you can for the least effort. Never mind the hard work . . . a concept we left behind back in the 1950s. That's something

those lousy, rotten Asians do when they sneak into our country and become successful, while we're gradually losing our quality of life.

Is change possible? Or are you too solidly inculcated with the baby-boom rationale? Are you too involved with TV, a little rag-chewing on the air, a rented movie once or twice a week, ball games, maybe some bowling? If I some way could find some people to write articles on new technologies that were written in a language you could understand, would you take the time to read 'em? Let me grind that one in a little harder. If I could get such articles and publish 'em, would you allocate a half hour or so at club meetings to discuss 'em? Okay, that's going too far. Maybe I should continue to publish feel-good articles and stop poking you with a stick.

When I point out that I'm not asking anyone to do something I haven't done myself, I get angry stares. Egotistical braggart. When I point out that it's exciting to get up on a mountain and make 10 GHz contacts with seven states . . . and that the equipment it takes is inexpensive and easy to build . . . I get shifty glances. I had a ball pioneering RTTY. Ditto SSTV. Ditto SSB. Ditto NBFM. It was fun learning. It was even more fun doing. And here we are in 1993 and there are more incredibly exciting horizons for us than ever before. Meanwhile, most hams seem to be looking backwards. Looking back fondly at Morse code, the

The ears have it!

“The R8 is like a breath of fresh air, with its ground-up engineering and up-to-date digital control from the front panel. I am very pleased to see a quality HF receiver of American manufacture that should successfully compete on the world market.”

*Bill Clarke
73 Amateur Radio Today*

When we introduced the American-made R8 Worldband Communications Receiver, we knew it would be judged by some very discerning ears, experts accustomed to the finest in short-wave listening equipment from around the world. After listening to the world on the Drake R8 loud and clear, they have delivered a decisive verdict.

They appreciated the R8's sensitivity, clarity, simplicity, and all-around versatility so much that many of them declared the R8 simply the best of its class. High praise, indeed, from very well-traveled ears.

But why take the word of mere

experts? Put the Drake R8 to the test yourself with a 15-day money-back trial period on factory direct purchases, and let your ears be the judge. If you're not impressed by Drake's quality, performance and ease of operation, all in a receiver costing less than \$1,000.00, return the R8

Receiver within 15 days, and we'll refund your money in full, less our original shipping charge. To order your R8 factory direct, for more information, or for the dealer nearest you, call **1-800-723-4639** today. We're confident that once you've listened to the R8, your ears will hear of nothing else.

CIRCLE 147 ON READER SERVICE CARD

communications medium of the 1920s and 1930s. Looking back lovingly at our archaic license structure, which is collapsing around us. Our national society is a radio relay league, aptly named when relaying was the only way to cover much distance by radio . . . around 80 years ago. Bummer.

New Hampshire and the 21st Century

An invitation came from Congressman Dick Swett (D-NH) to a meeting in nearby Keene proposing the organization of a 1994 National Information Technologies Conference at Keene State College. Swett spoke to (and with) the group via satellite video from Washington. We could see him, but the video was one way, so he couldn't see us. We could hear him just fine, but he had trouble hearing us, and then the audio link was lost.

There were around 25 business and education leaders present. We struggled to try and understand just what Swett or anyone involved in the project thought an Information Technologies Conference would involve . . . what the benefits would be and to whom . . . and who was going to pay for all this. There seemed to be a good deal of confusion about this. Swett read a long, prepared Beltway language speech . . . a lot about pro-activity. I'm pretty good at translating various American dialects into plain English, but I got lost. So did everyone else, fortunately. I'm not exactly sure what pro-activity is, but I'm all for it,

and it describes me to a tee.

There were some vague references to information technology somehow benefiting local businesses, which is almost obvious enough not to have to be defended. And there was the need for Keene State College to start producing the information technology work force local businesses are going to need.

The hope was that Keene State and the local business leaders would work together to organize the conference. There was some mumbling about getting federal funding, but first they needed \$50,000 from the business community as seed money to get the project started. This would take care of the next three months, when they hoped federal funding would kick in. Hmmm. Fifty big ones for three months? The obfuscation almost smothered us, but I think what they had in mind was sending someone or a small group around the world to look into information technology elsewhere. There was some mention of site selection. I quickly offered to handle the site seeing part of the project for them as soon as they had the \$50G, pointing out my extensive qualifications and contacts in the communications community everywhere in the world. I don't think they heard me. Perhaps they already had some volunteers with their eyes on the \$50G.

Far's I could see, the local business community was much more interested in the fruit and cheese plate than do-

nating to this phantom project. But hey, you never know. The last two times I volunteered to go on expense-paid around-the-world trips I won out, so my foot seems to automatically extend at the slightest hint, looking for any running boards to climb on . . . so to speak. You remember running boards, right? You've seen 'em in the old movies, with gangsters hanging on, shooting.

Yes, it would be nice if Keene could attract some of the coming high-tech manufacturing that the communications and information technology industries will make possible. And if Keene State could help provide high-tech career workers, the chances are good that the area would benefit from this by attracting such businesses. They'd better start working out some methods for helping to finance these startups though, otherwise they and the workers will go where the money is.

Of course adding some technical courses to a state college isn't going to do squat. They've got to train teachers and get the New Hampshire K-12 schools to change. Big change. You don't become much of an engineer, technician or scientist with a couple years of college. You need to get started when you are in the 5th grade if you're going to go anywhere and do anything. That's why I keep nudging you to visit your local schools and fire up the 5th graders. Get 'em excited. Get these noisy, bothersome little nui-

sances to your ham club and poison their dirty little minds with our fascinating hobby. It happened to me, and like all such addicts, I want to spread the misery.

Swett promised that if we organized a national conference he'd try to get Clinton to come. And if he failed with that, to get him for us via TV. Failing that, he'd push for some other high official to come or at least address us via closed-circuit TV. Let's see, who's the new janitor at the White House?

I still haven't a clue as to what the site investigation team was expecting to find out on their \$50G trip. I did miss out on a great opportunity. I wish I was faster on my feet on these things. I should have jumped up and started a collection plate around, pledging \$10 to get the fund going. My life is full of missed opportunities like that.

You Read It Here First!

Some time back, when I wrote about homosexuals in amateur radio, I got several heated letters from Bible-thumping religious fanatics. They were incensed that I'd suggested that there was a genetic element to this deviation from the norm. By the way, homosexuality is just one of a wide variety of deviations which cause people trouble. Being too tall, too short, too stupid, too intelligent, too ugly, too pretty, too skinny, too fat, too buxom, too flat-chested, and so on . . . all the "loos" . . . are deviations that we don't

take with grace and understanding. We also make fun of deviant ears, noses, hairlines, and so on. Ask Perot.

The overwrought were upset at gays (aka homos, queers, fags) advertising in ham magazines, seeking members for their gay ham society, Lambda. I pointed out that science had shown that there seems to be a genetic predisposition for gayness and that my own research in the field had shown that the gays I worked with had had these feelings from their earliest memories. In my work I've been able to trace back virtually all psychological abnormalities to specific triggers during painful childhood and even prenatal experiences. A few were resolved by taking a tolerant approach to past life "memories." But gayness, in the cases I worked with, didn't fit into the normal psychological trigger pattern. It seemed to have a genetic basis. It's therefore interesting that recent scientific genetic research has confirmed this.

Now, I'm not by any means saying that all gay activity is genetically manifested. If you're at all read in history you know that in societies where homosexuality was condoned, it was widely practiced, so obviously there's a strong psychological component involved. So, though we may abhor the practice of homosexuality as a cultural bias today, we can't help being sympathetic to those who are genetically driven, despite society's censure.

It's the male homosexual lifestyle that attracts the most outrage and the

least sympathy when AIDS strikes. Kinsey's research showed that while the average lesbian has less than 10 sexual partners, the typical male homosexual in America has had over 500! We know that male sexuality is much more destructive than female when not controlled. Men rape, not women. Only men engage in fetishes. Only men are sexually sadistic. Men far more often wander from partner to partner.

It was Judaism that changed things. Judaism, and its spin-off, Christianity. Up until then homosexuality was accepted. It was exalted in Greece, commonly accepted in Rome, and is still popular in the Arab world. It was prevalent among the pre-Columbian Americans, the Celts, Gauls, pre-Norman English, Chinese, Japanese, and Thai (see *The Public Interest* #112). So here in America we've been inculcated with the Jewish/Christian beliefs. I'm not sure that even recognizing that we've been brainwashed by our religious training will allow many of us to be tolerant.

So we hams are outraged when we learn that some of our outstanding hams have been convicted of molesting young boys. Indeed, one of our best-known repeater pioneers was convicted of this, as was one of our major ham convention luminaries. And so we naturally react with suspicion when we see ads aimed at attracting youngsters to a homosexual ham group.

And now we're learning that Catholic priests have been having sex

with and even raping altar boys without any significant reaction by the church when it's reported . . . other than to transfer the offenders to a new area . . . much to the frustration of the families involved.

The militant feminists haven't helped things. Men and women have some powerful basic differences, which many feminists try to deny. For instance, men, when they are born, are much less amenable to socialization than women. They're four to six weeks behind neurologically, and need more care. They're more likely to be hyperactive, autistic, color-blind, left-handed, and prone to learning disorders. They tend to be much more affected by the mother's prenatal use of drugs such as tobacco and alcohol. In every society men play more roughly, drive more recklessly, and fight more than women, and these traits appear early in life. Archaeology tells us that in prehistory about 25% of all males died in fights . . . about the same as anthropologists have found in recent years with primitive tribes.

Men, as they grow up, are much more likely than women to cause trouble in school, be alcoholics or drug addicts, and commit crimes. And by the way, there is no historical evidence to show that there's ever been a society ruled by women.

Just as the militant feminists are prone to name-calling, so are many of the militant homosexuals. They use the term "homophobic," yet no such phobia exists in any medical list of phobias.

This is demagoguery and makes as much sense as shouting back that they're women-phobic. It's McCarthyism repeating itself.

Judaism was a breakthrough religion in that it focused on the family. Its prohibition of non-marital sex changed the world. This was carried on later by Christianity. Both religions condemn homosexuality, incest, and bestiality.

If we look to Mother Nature as a guide, where one of her basic rules is to be fruitful, homosexuality fails. So I have no personal problem with consenting adults enjoying what pleases them as long as they don't mess with unconsenting adults or children.

Having served for four years in the Navy, I had a good laugh over the spot Clinton got himself into by catering to the militant gays and promising them out-of-the-closet military careers. Clinton, not having served in our military, didn't know what he was getting into. And sexuality being what it is, as anyone who's read much about our prisons knows, announced homosexuals in the military could easily create trouble.

I went to sea for five war patrols during WWII with a crew of about 80 other sailors. We were all men and good buddies. We still get together every year to remember the good and bad times we had 50 years ago. But if we'd had some gays sleeping right next to us in those crowded quarters, it could have created tremendous tension. And probably fights . . . something we sure didn't need on a submarine.

AEA

AEA has recently introduced the IT-1 AutoTuner, an accessory for their popular IsoLoop 10-30HF antenna. The IsoLoop is a high-quality, high-efficiency antenna with a mere 35-inch diameter.

The IT-1 AutoTuner will automatical-

ly tune an IsoLoop in just a few seconds. When more control is necessary, there is a thumbwheel for manual tuning and fine adjustments.

The IT-1 AutoTuner features a 12-button keypad with an audible beep to announce completion of tuning. It has eight programmable memories as well as a 10-segment LED bar that monitors the tuning process and indicates the selected memory number. Memory backup and a built-in serial interface are also included.

The suggested retail price is \$279 at your local amateur radio dealer. The unit comes with a one-year warranty. For more information contact: *Advanced Electronic Applications, P.O. Box C2160, Lynnwood WA 98036; (206) 774-5554, Fax: (206) 775-2340.* Or circle Reader Service No. 201.

CREATIVE CONTROL PRODUCTS

Here is a brand-new, low-cost, easy-to-interface repeater audio interface circuit from Creative Control Products. The UAD-100 Universal Audio Delay board features complete DTMF tone mute, and squelch tail elimination.

This board is inserted in the repeater receiver audio path before any audio switching circuitry. It then delays the audio before it arrives in the repeater transmitter, resulting in a pleasant-sounding transmitter drop. No more crashing, clunking, or snapping. Finally, a great sounding system, made easy.

The UAD-100 comes fully-assembled and tested, with a detailed application manual and one-year warranty, for \$99. For more information, please contact: *Creative Control Products,*

3185 Bunting Avenue, Grand Junction CO 81504; (303) 434-9405. Or circle Reader Service No. 203.

M²

The new Orion OR-2800 Antenna Rotator from M² is conservatively engineered for long life and reliability while turning large antennas or systems of up to 35 square feet of wind area. New features include a strong, ductile iron

mast clamp, large drive plate, improved drive shaft, and prop pitch style torque plate. The powerful motor and large heat-treated gears provide 2,500 inch pounds of torque. Vertical load capacity is 1,800 pounds. The unit can accommodate up to 3-inch o.d. masts and fits nicely with most popular towers and rotator plates.

The RC2800 Control Box provides the finishing touch. It has digital readout, variable speed control, slow start, reverse delay, and memory protection. The optional RC2800P adds programmability, two-rotator control, AZ readout, and other features.

The OR-2800 Rotator is manufactured in the US by M² and carries a one-year warranty. The suggested retail price is \$1099. For more information, contact: *M², 7560 N. Del Mar Ave., Fresno CA 93711; (209) 432-8873, Fax: (209) 432-3059.* Or circle Reader Service No. 205.

JENSEN TOOLS

Wouldn't it be nice to always have an entire tool chest right at your fingertips? Well, now you can have the next best thing—the new SOG ToolClip from Jensen Tools, Inc. This unique pocket tool combines 13 functions in one neat little package.

The SOG ToolClip features a full-jaw pliers, a combination gripper and wire cutter that can easily handle chain-link fencing, a razor-sharp spear-point blade, a utility blade, a serrated-edge blade, a pair of screwdrivers, a pair of wire strippers, a file, a pry bar, and a bottle opener, all in a sturdy housing complete with a belt clip. The pliers, wire cutters, and grippers can all be accessed with only one

hand—a mighty helpful feature when climbing towers or holding materials.

The SOG ToolClip is constructed of durable stain-resistant steel and is guaranteed for life against defective workmanship and materials. The price is \$59.95. For more information, or to receive a free catalog, contact: *Jensen Tools Inc., 7815 S. 46th St., Phoenix AZ 85044; (602) 968-6231.* Or circle Reader Service No. 202.

TRIMBLE NAVIGATION

You'll never get lost again with Trimble Navigation's satellite-based handheld GPS (Global Positioning System) Scout. It is perfect for amateur radio applications, search and rescue, backpacking, and off-road driving. The low-cost Scout GPS receives positioning data from 24 orbiting satellites to pinpoint your location around the clock, anywhere on earth, in any weather.

The GPS was designed and developed by the US Department of Defense to benefit both military and civilian users. Hams will enjoy the Scout GPS, which is based on the Maidenhead Grid Locator, displaying location information in language familiar to many amateurs. Scout uses the ARRL's grid square locator technique.

The Scout GPS kit contains four AA batteries, a user's manual, cordura carrying case, lanyard, and the Trimble Atlas. The whole package retails for \$795 and an external antenna

kit accessory is available for \$150. For more information contact: *Trimble Navigation, 645 North Mary Avenue, P.O. Box 3642, Sunnyvale CA 94088-3642; (408) 481-8000, Fax: (408) 730-2997.* Or circle Reader Service No. 204.

JADE PRODUCTS, INC.

Jade Products' Fun-Kit EK01 Experimenter Board provides a unique solution for the amateur radio builder. With this prototyping parts kit the novice and the seasoned experimenter can design numerous circuits. The kit contains a general purpose PC board engineered specifically for RF and other radio-type projects. Also included are three versatile ICs used in RF design, mounting hardware, a handsome 7.5" x 8.5" x 3.5" enclosure, complete assembly in-

structions, and building suggestions.

The 5" x 7" PC board consists of four general areas: a digital device area for active filters, keyers, logic, battery chargers, line drivers, etc.; an RF power area with 0.20" solder pads to mount discreet devices such as capacitors and inductors—ideal for QRP transmitter designs; a transistor device area with three footprints for circuits such as VFOs, buffers, and crystal oscillators; and a dedicated circuits area featuring the NE602AN mixer/oscillator chip, an audio amplifier circuit using the LM386, and etch support for the Motorola MC1496. The enclosure is finished in pleasing neutral colors.

The price is \$44.95. For further information, please contact: *Jade Products, Inc., P.O. Box 368, E. Hampstead NH 03826; (603) 329-6995.* Or circle Reader Service No. 206.

David Cassidy N1GPH

ARRL At It Again

Once again, I am forced to inform you of the sneaky goings on down in Newington. Like so many of their actions in the past, actions made on *your behalf*, you won't be reading about this in *QST*. I sure do wish I didn't have to keep doing this, but I feel that it is important the amateur radio community gets an accurate picture of the organization that supposedly represents all of us.

As you may remember, the FCC now has authorization to allow a private organization to administer the issuing of special club and military call signs. The rules state that any organization seeking the right to issue these special call signs must (among other requirements) be tax-exempt under the IRS educational designation and exist for the purpose of furthering the Amateur Radio Service, demonstrate that its membership constitutes at least 1% of FCC-licensed operators (that would be about 6,140, as of this writing), and process applications without regard to race, sex, religion, national origin or membership status in any particular organization. Pretty simple, right? Not according to the ARRL.

The ARRL (surprise, surprise) thinks they should be the *only* organization allowed to issue these call signs. They tried to get the law written in such a way that would exclude all other organizations, but their sneaky tactics were discovered in the nick of time by Fred Maia W5YI. Fred got the wording changed, much to the League's chagrin. Oh, you never read about that in *QST*? Must have been a computer error, because I'm sure the ARRL would have made every endeavor to inform their members of such an important issue.

The FCC received applications to issue club call signs from five organizations: the ARRL, W5YI-VEC (whose tax-exempt status has been accepted by the IRS, but a number has not yet been issued), the Quarter Century Wireless Association (remember, it was the QCWA who licked off the League by coming up with a simple, elegant and workable no-code proposal, which effectively killed the ARRL's convoluted and complex plan), the Southeastern Repeater Association and the National Amateur Radio Organization. On August 6 of this year the ARRL also filed a 24-page "Opposition to Requests for Designation of Certain Entities as Club and Military Recreation Station Call Sign Administrators." In this document, the ARRL objects to all four competing organizations' applications.

The League doesn't like W5YI-VEC because their tax-exempt status has not yet been issued. The League also objects to the fact that W5YI-VEC changed its corporate status from two divisions of the same company to two separate corporate entities, one of which is to be tax-exempt. I'm surprised that the ARRL used this flimsy objection, since it is similar to what they had to do, as publishers of license testing literature, when they wanted to start the ARRL-VEC (another time in the recent past when the

League tried and failed to block all other organizations from participation).

The ARRL doesn't like QCWA because it is a social club and, according to Newington, is organized for pleasure and recreation rather than education. The League also mentioned that it doubted the QCWA could handle the assignment of club call signs with a single employee.

The Southeastern Repeater Association is being blackballed by the boys in Connecticut because they filed their application by fax at a time when the FCC offices were closed for the evening. The League also states that a facsimile transmission does not constitute a legal signature, and that the SRA doesn't have the required 1% of all licensed amateurs as members.

The ARRL questions The National Amateur Radio Association's claimed membership of over 7,000 and its function as anything more than a very limited magazine publisher, subscription to which constitutes membership.

This move by the ARRL to block any other group from administering any part of amateur radio is not new. Time and time again, the League has spent your dollars to fight *their own* personal battles and agenda. Only when the League is successful do the members hear about how the all-knowing and benevolent ARRL has wrought something wonderful. When the League fails at their power grabs (as in the case of the VEC program and the authorization bill that started this call sign administration program), the members are never informed.

I have been accused of being a League-basher. This is simply not the case. Most of the people who I come in contact with who work for the League are great folks. Really! The problem is the folks in charge. Remember, the fish always stinks from the head down. I'm sure that all the folks at the upper echelons of the ARRL are nice, law-abiding people who are kind to small children and puppies, say "please" and "thank you" and always remember their mothers on Mother's Day. I do not question the personal qualities of any individual. The organization as a whole has lost its way. They have stopped looking out for the interests of amateur radio and are now only concerned with the interests of the ARRL. Unfortunately, they long ago convinced themselves that the two are the same thing.

The ARRL must be accountable to the very people it claims to serve. I don't think any criticism I've ever leveled at the League has been ungrounded. I've received a lot of mail about my opinion of the ARRL, but never once has anyone presented evidence to show that I was wrong. My deepest hope is that, with the passing of the old guard, a new generation of hams will rise forth to reclaim a once-proud heritage.

Until that day arrives, a simple question remains: Since the ARRL claims to be "of, by and for the radio amateur," how come so much of their time and your money is spent on fighting for control of amateur radio instead of solving the problems of amateur radio?

Payson AZ 85541

In general, the month of October is expected to provide GOOD propagation. The chart shows POOR days on the 14th, and from the 17th through the 20th. The remainder of the month will provide days trending around FAIR in both directions. October exhibits the usual fall conditions; that is, on the 10, 12, 15, and 17 meter bands, you should find some excellent conditions for worldwide DX on the days of the month marked GOOD. In particular, the higher the band, the more frequent north-south path openings; and the lower the band of this group, the more frequently you will find east-west openings. The higher bands will peak in the afternoon, following the sun westward from your location. Twenty meters will be your best DX band, with dawn to dark openings to almost every area of the globe.

Signals won't be quite as strong as they were earlier, in the peak of Cycle 22, but they will be very acceptable. On 10, 12, and 17 meters, you will find occasional F2-layer openings and sporadic E-layer openings where signals can peak for as long as a half hour and then suddenly disappear as the electron "cloud" drifts out of the skip range. The lower HF bands of 30 and 40 meters will exhibit some slightly different behavior. They will be your evening and nighttime bands, with DX to your east toward Europe peaking around midnight, and to the west toward Asia and the Pacific in the early morning hours around local dawn.

Thirty meters will close earlier for within-U.S. short-skip, and you should be able to work DX at local dusk. High absorption during the daytime in summer always limits skip contacts, but this month the absorption will be less and good daytime skip signals should occur on the GOOD days, with high levels. As always, thunderstorm activity will cause QRN, but that problem is expected to be much less in evidence now as we move toward winter conditions.

On 80 meters, you will find some good DX from evening to

dawn, very often to the Southern Hemisphere, and good daytime short skip in the absence of thunderstorm activity. For you top-banders, 160 meters will be best for the hours of the evening, peaking for DX around midnight and again at dawn. Also, nighttime short skip openings will be excellent on the GOOD—and ever some FAIR—nights, out to about 2,000 miles or so.

As we've said before, keep your eyes and ears open on those days marked POOR, as other manifestations of a disturbed magnetic field may occur, such as hurricane-force winds, volcanic eruptions, "freak" weather, and even "quakes." Obviously, they won't always occur, even when they do, it is difficult to determine where they will occur. Pay particular attention to 19th and 25th, and to 1 day on either side of these dates. Let me know how the forecasts work for you. W1XU

NEVER SAY DIE

Wayne Green W2NSD/1

Amateur Radio Frontiers

There are still plenty of frontiers for the adventurous ham to explore and pioneer. Everything hasn't been invented, by a long shot. Indeed, there are tons of articles I'd love to see published in 73, if only you'd write 'em.

For instance, I've seen pitiful little in recent years on slow-scan developments. We need to (a) digitize slow-scan so we can send some really detailed full-color pictures, and (b) use modern compression technology to keep the bandwidth down. When's the last time you saw any articles on things like this? What do you need to get your mind working and your fingers busy? With the progress we've had in slow-scan technology in the last few years, any interested ham with totally zero technical knowledge and a will could have come from zero to being the top expert in the field. All it takes is some interest and the determination to overcome obstacles.

When I first got interested in RTTY I knew zilch. But I was fascinated, so I read everything I could find . . . which wasn't much. I hounded the only expert in the field I knew, John Williams W2BFD. I built my own equipment using John's designs, a Model 12 Teletype machine he got for me, and got on the air. Wow, what fun! This was when I first learned about digitally encoding information and the ability of frequency-shift keying to get through interference far better than off-on (CW) keying.

Teletype used a five-bit code, which meant that there were just 32 possible combinations of zeroes and ones, or marks and spaces, as we called them. This is why telegrams and news Teletypes all used to print in upper-case letters. We didn't have any lower case. We even had to shift to handle numbers and punctuation. This is why ASCII code, which all computers use today, has eight bits. This allows 256 combinations of zeroes and ones, giving us far more flexibility.

When I couldn't get anyone to put out a newsletter to help us pioneers learn more about RTTY I finally gave up and did it myself. Indeed, that's what got me into the publishing business. I called it *Amateur Radio Frontiers*, and that was back in 1951. I wrote it, drafted the schematics, sold

the advertising, took the photos, set the type, pasted it up, handled the subscriptions . . . everything. It was incredibly valuable experience, and it changed my life.

Digital Compression Systems

With modern microcomputers it's relatively easy to digitize pictures. You can feed 'em into your computer from a home video camera or a scanner. But a decent picture can take a megabyte or more of memory, which is why we haven't been seeing much in the way of live video digitized yet. At 30 megabytes per second, that eats up a whale of a lot of memory in a hurry, no matter what you're using for storage.

So, the engineers have been working to compress the data, using various approaches (algorithms). The International Standards Organization's Joint Photographic Experts Group (JPEG) uses a discrete cosine transform which compresses files by 90-95%, giving us ratios of 10:1 to 20:1. Iterated Systems of Norcross, GA, went the fractal route and has been able to compress data around 75:1.

Fractals? If you haven't messed with these babies you've missed a whole new world of math and beauty. IBM's Mandelbrot got interested in chaos theory a decade ago and discovered that seemingly chaotic systems produced similar patterns when plotted. He called the resulting patterns fractals. Computer owners with color displays can generate these beautiful patterns. If you aren't familiar with fractals and chaos theory, you're letting the real world get away from you. As hams, you're supposed to be up on science and electronics. You're not flying under false colors, are you?

So, let's see some articles on digitized slow-scan pictures. Let's see some articles on the theory and practice of compression techniques. And, let's see some protocols for digital slow-scan.

If we can at least send our American standard video picture quality (NTSC) by digital slow-scan, then we can start working on ways to move to high definition slow-scan. One step at a time. More and more of us are buying high definition color monitors for our computers, so we've got the mak-

ings of some wonderful slow-scan pictures.

You may not be an expert on digital video now, but by next year are you going to be even further behind? Or will you be one of the people writing the articles? When I got started publishing my RTTY newsletter it didn't take long before I knew what I was doing. A few years later I published the first book on ham RTTY. In the meanwhile my columns in *CQ* helped get thousands of hams involved with this fun part of the hobby.

Digitized Voice?

With all broadcast radio going digital, as well as TV, we hams better start thinking in digital terms or we're going to be as far out of date as if we were still using spark gaps for our CW. Yes, I know, many old-timers are still upset over having to change to sideband 30 years ago. I think all of the "spark forever" crowd have finally won their Silent Keys certificates, though they were still a grumbling, resentful bunch when I started hamming in the 1930s.

With digital broadcast test stations showing three times the signal coverage with a hundredth of the power . . . plus the ability for six different stations to share each channel . . . digital is definitely coming. Sideband gave us six times the bang for the buck over AM, plus it allowed more stations per kHz. It certainly met the rule of thumb criterion for a new technology to be 10 times better than the old in order to survive. Well, so does digital, so nothing can stop it.

With that in mind I'd like to see some special temporary authority (STA) hams experimenting, complete with articles for 73.

Data Compacting

In addition to the usual search for compressing algorithms, we might start setting up some protocols for packet and RTTY which would compress our transmissions. This doesn't even have to be high-tech. CW ops invented the Q-code to shorten their transmissions. So how about some simple look-up tables our computers can use to cut down on redundant messages? A sort of packet approach to the Q-code? For instance, "N>" might translate into "the name here is."

We could even simplify names a bit with "Bob" being "bb" and "Bill" being "bl," Wayne being "wn," and so on. That would speed up the more common names.

With data compression we should be able to get contacts down to a few seconds of air time. "rv" could mean "the rig here is an ICOM 735." The second character could indicate up to 256 different models of rigs. Ditto for antennas. Yes, "q" would mean "I faithfully promise to send you a QSL card for this wonderful contact and hope that you will send one in return." A "w" with one added character would indicate up to 256 different kinds of weather, thus slicing at least two to three minutes of air time from every contact.

In this way we'll be able to make several contacts a minute and then read the expanded copy later when we have time. Few of us bother to comment on anything the other chap is saying anyway, so what's lost? The only really significant element of the contact is making sure you have the call right. You've got the *Callbook* on a CD-ROM, so you don't really need a location, unless he's portable.

With data compression we'll be well on our way toward completely automatic contacts. We'll be able to get reports from our computer on who we've contacted while we're at work or sleeping. Or watching ball games or TV. I'm reminded of RTTY back in 1950 when I'd come home from work and pick up 50 feet or so of printout and read what'd been talked about or the RTTY channel all day.

If we do find something of common interest we can send prewritten documents from our computers. In the old days we'd punch Teletype tape with stories we might want to repeat. When there was an interest in some subject we'd load the tapes into the reader and they'd zip through at 60 wpm. It's a little easier today.

Oops, We Lost 100,000 Hams!

Just when we were all getting our arms out of joint congratulating ourselves on boosting our numbers to 600,000 licensed hams (FCC count) we get the bad news that the ARRL has done a survey and found that 16% of us are missing. Holy jumping Morse code, that's a hundred thou, piff! How'd that happen?

Well, as I've been reminding you and you've been ignoring, the FCC no longer bothers to delete our Silent Key award winners, nor our bored or unemployed dropouts. And with our licenses now good for 10 years, there's a lot of buried ham in the *Callbook*. Tons.

So, even with the increased input or no-code hams, are we breaking even? Maybe, just.

In looking over the ARRL survey, it seems like we have an awful lot of old-timers with a serious death wish for our hobby. I can't spread a lot of guilt on you because the chaps who are the problem don't read 73. Most of them hate it.

Continued on page 76

From The Hamshack

Dick Beaton N7RB, Helena MT Wayne—As an old CW op, I'm not going to jump in and tell you that we have to keep all those CW frequencies or that CW is sacred. As a useful means of communication, it is a real dud. It's fun if you like it. It is hard to believe the ARRL still promotes traffic handling on phone and CW when packet will do it better and faster.

I was licensed in 1934 and worked as a CW operator in the CCC camps in North Dakota. Would you believe I lumished my own home-brew station? It was that job that helped me get a job with Northwest Airlines, first as a radio operator in '38, and later as a station manager in '42. We even used CW for handling reservation traffic from 1939 until about 1944! Before that it was all AM phone!

Well, anyway, I was one of the first around here to promote the no-code license idea. I've also been promoting your method of learning the code. I've taught code off and on for years and was one of the first VEs around here; also among the first on packet. At least in my case CW hasn't scrambled my brains and I could easily prove it. I don't get on as much anymore as most guys just won't talk. And I'm with you on QSLs! If a DX station gives me that old "QSL via a bureau," I just tell him "no QSL needed." They used to come with neat stamps on them. Now they are just another card in the drawer. (How about using packet for QSLs and making an excuse for sending traffic?) I don't even know how many countries I've worked and could care less. It isn't a big deal anymore. I do have WAS on Geritol net 3767 kHz. The only thing on my wall is a Kenwood world map and my "Ham of the Year" plaque from the local club.

One thing you could quit harping on is DXpeditions. The real truth is that very few of the hams I know could afford such a thing. Your background gets you into places that are out of reach to most others, so please quit comparing yourself with the rest of the hams. You are one of the privileged elite. As a VE, I know that some people have a tough time coming up with five bucks. I know how it is because I was one of them. You weren't.

When I was a kid we used to get the battery out of our Whippet to light the filaments in the old four-tube regenerative radio with a horn speaker. The problem was we went without radio a lot because the "B" battery didn't last very long. I set out to "invent" a substitute without spending any money because I didn't have any and my dad was on WPA. I succeeded, too! I didn't exactly know for sure what I was doing, but I ended up using a doorbell transformer to light the 201-A filament. I used one side of an audio transformer for a choke and the capacitor out of a Model T Ford coil for a filter. The plate and grid were tied together to make a diode that rectified the 110 AC. It worked like a charm.

After WWII I went through a lot of surplus gear modifications, etc. I never had an AM rig, just home-brew CW until the HW-101.

The mess on 14.313 makes me ashamed, but I have resisted the temptation to jump in and tell them off. It must be the big amplifiers those guys use that screws up their brains. I don't think the Extra Class license did it. I've got an amplifier, but haven't had it hooked up for a long time. Those old dudes who do talk don't have anything good to say, anyway. I used to check into the QCWA net in Montana and all those old guys do is talk about their health complaints and the weather.

Incidentally, you wanted to know what new products we use. Well, I had an R-5 vertical which worked great but was limited to bands higher than 40 meters, so I sold it and bought a GAP. It works fine, too, but on 80 the low angle of radiation makes it useless for visiting with guys within 100 miles or so. I tried to put a Biall in the attic here without any success. Our attic goes up through a hole in the hall closet, so I had to give up trying to make it work. It doesn't even look like it should work!

I'm 76 years old and sorry I'm going to miss all the wonderful new things just over the horizon. Then again... I've lived to see one helluva revolution in the world of scientific knowledge. I missed a lot because I went to the college of hard knocks, but I think I know a lot more than quite a few college grads who never learned anything very useful.

One last thing: Hope you succeed in getting the school system fixed. Everyone should know Ohm's Law and DOS.

73 to a great editor. You and Rush Limbaugh should get together! You have a lot in common.

Dick—Elite? Me? Har-de-har. I've never been on a DXpedition that cost much. Travel is mostly a matter of decision. It doesn't have to cost a lot. For instance, Sherry and I spent a week in Rome last month. Wow, that must have cost a bundle! Well, we flew business class, stayed in a very nice hotel, went everywhere, saw everything, had some great dinners. Now how much would you budget for a trip like that, total?

The flight, hotel, meals, taxis, tips, and everything for a week came in at \$551. A couple years ago we flew round-trip to Munich business class, rented a car, drove to Vienna, Krakow, Prague, and back to Munich. First class hotels. Fine meals. Two weeks. The total cost was under \$1,000.

Of course I was able to do some business on each trip, which more than paid the cost of the trip. In Vienna I signed a contract with an Italian publisher to use 73 articles. In Rome I made import agreements with two record companies. Travel doesn't have to be expensive if you do it right. And that includes DXpeditions.

How much does it cost to drive to Halifax? Peanuts. Then there's the short flight to St. Pierre. The hotel was ridiculously inexpensive. So were fabulous meals. So we DXed there for a few days.

Any ham who has trouble coming up with \$5 sure isn't much of an entrepreneur... and isn't using his ham know-how for anything but his own fun. There are too many easy ways to make money these days for anyone to be poor... unless they've been too lazy to get an education. Maybe you've noticed that there are very, very few well-educated poor people... and very few poorly-educated rich people. It's almost enough to make someone think.

College is a waste of time, no matter what you want to do. You can learn 10 times as much in half the time on your own. But then you want to keep right on and not stop. I'm still learning. I've read over 100 books in the last few months and have 50 more by my bed being read. No fiction... Wayne

Matt Thomas N8TWF, Ortonville MI I am writing to you because a few hams have really made me sick. I was scanning the 20 meter band not too long ago and heard a small group of hams cursing and swearing like mad on 14.315 MHz. What kind of representation of our great hobby is this? If I were a shortwave listener thinking of getting a license, this would probably convince me to change my mind. The only place I have heard more cursing is at school. I thought hams were to promote international good will. In my opinion, this hardly promotes international good will.

By the way, I really enjoy reading "Never Say Die." Wayne, you have some interesting opinions.

John R. Lowther, II, Lawrence KS I am writing in response to your "Never Say Die" column in the June 1993 issue. I have been a sporadic reader of 73 for years and your column is often the most interesting part of the magazine and certainly the most unpredictable.

In this column you hammered on one of the problems which has been keeping me from seriously pursuing an amateur radio license: There seems to be hardly anyone out there worth talking to. When I listen on the ham bands with my little Sony 2010 I find very little worth listening to. Using the receiver section of my elderly Drake TR-4C I find nothing more, despite its superior ability to separate one signal from the next.

I went through a study guide for the no-code Technician license and was surprised to find that the so-called "significant technical requirement" consists mostly of extremely basic electronic theory that anyone who has actually done anything with electronics should already know.

Of course, the no-code Technician license is not all that interesting, lacking privileges on the HF bands capable of reasonable reliable long-range contacts. Even with the addition of passing the 5 wpm Morse code test, only the 10 meter band is available for telephony, the other bands allowing only digital communications (including that most primitive of digital systems, CW).

If the ARRL cannot be pried away from the old incentive licensing scheme, perhaps the privileges for using manually-generated Morse code can be separated from the other privileges of the license so that having once passed the 5 wpm code test (3 wpm would be better), to meet the re-

quirement of the treaty, you would gain all of the General Class privileges upon passing the General Class written test, except on frequencies designated for emission type A1A, only gaining A1A privileges on passing the 13 wpm code test, and likewise to the Advanced and Extra Classes.

This proposal would be consistent with the objective of the amateur radio service as a source for skilled electronics technicians, as it would provide rewards for gaining additional technical knowledge without holding the acknowledgment of their advance in knowledge hostage to skill in using an obsolescent (and I am tempted to say obsolete) communications technique.

Eric P. Nichols KL7AJ, North Pole AK Here's an interesting figure for you. I recently acquired an HF packet station (actually a by-product of the AMTOR station I wanted). At any rate, I opened up all the AX25 monitors and tuned to the 14.103 MHz PacketCluster, letting everything spill its guts out of my page printer. After a six-hour period, I did some statistics on the printout. Lo and behold, 98.4 percent of all printed matter was "overheard," i.e. addressing an error-correcting information. The remaining 0.6% of the printed matter was actual text. So, the point is that inutilities are not restricted to phone bands, they are built into the very soul of packet radio! A little food for thought!

One nice thing about packet, though, is that I can selectively reject calls from such unwanted areas as Japan. I call my program my "JA notch," and it saves a whole lot of wasted time and effort. Back in my phone days I used to call "CO nc JAs," but someone told me that was uncouth. Packet allows me to be selectively rude (or rudely selective) with no guilt!

Mind you, I have nothing against Japan per se, but if you have ever operated in Alaska you will know that JAs are about all you can get without extensive maneuvering... they literally swarm the high bands. Most KL7s rely on vast quantities of front-to-back ratio to solve the problem, but that leaves something to be desired in case you want some desired Asian country!

By the way, I have devised a new more efficient signal reporting system one in which the typical QSO is contained within the report itself. The report has two numerals and two letters. A typical QSO might be like this:

"AL7HC, this is KL7AJ. Your report is 59YR."

"KL7AJ, this is AL7HC. Yer' report is 57IS. 73s."

"73s. KL7AJ clear."

Translation: "AL7HC, this is KL7AJ, you're five by nine, the rig here is a Yaesu, and the weather is rainy."

"KL7AJ, this is AL7HC. Roger. Yer' five by seven, the rig is an ICOM, and the weather is sunny. 73s."

"73s. KL7AJ clear."

As you can clearly see, this four-character report is more than adequate for more than 98.4% of all amateur QSOs. For the long-winded, a third letter might be used to describe the current physical ailment: "H" for heart problems; "K" for kidney stones; "P" for prostate surgery, etc.

RF Radiation Feedback

The FCC has extended the comment period on a proposal (in E.T. docket 93-62) that the commission adopt new guidelines for evaluating the environmental effects of radio frequency radiation. The federal agency will hear comments until November 13 on the proposed guidelines, which are the same as those already adopted by the American National Standards Institute and the IEEE.

The FCC says the request for extension was made by the National Association of Broadcasters, and was supported by other interested parties. The NAB's request was to allow a study to develop non-measurement-based techniques for complying with the Commission's new rules. *TNX Westlink Report No. 656, September 1, 1993.*

Vanity Callsigns Authorized

Both the House and Senate have approved legislation authorizing the FCC to issue unique amateur radio callsigns, at a cost of \$7 per year, to the ham community. The surprise measure was inserted into the recently-signed deficit reduction bill of President Clinton.

According to a congressional aid close to the plan, "We envision that the legislation will probably be implemented so that an amateur pays \$35 every five years, although there is no language in the bill that says they have to do it that way. It only says they have the authority because they do not have this authority right now. . . . As I understand it, the proceeds will go to the FCC to augment their budget, . . . pay for equipment, staff, and stuff." The only amateurs who would be subject to the new fees are those requesting special, distinctive callsigns.

Another little-known tack-on to the deficit plan provides for spectrum auctions. The government is set to receive more than \$10 billion over the next five years when it sells radio spectrum to the highest bidder for new communications services. *TNX W5YI Report, Issue 16, August 15, 1993.*

Instant Ham

A petition has been filed before the FCC by the Western Carolina Amateur Radio Society VEC that seeks a rules change permitting instant ham radio licensing. Specifically, the Knoxville-based testing group wants the commission to amend Part 97 to allow amateur radio operating privileges to commence upon passing the required exam, without having to wait for the issuance of a first license.

The WCARS VEC argument states that anyone who holds a valid Certificate of Successful Completion for an amateur operator's license which was issued within a year should be authorized with the rights and privileges for that license class. They propose a temporary callsign structure based on the Class D citi-

zen's radio service precedent which was set several years ago under deregulation. Proponents believe this measure would save the government time and money they spend answering phone calls from those waiting for their licenses to arrive.

This proposal, designated as RM-8288 is open for comments to the FCC. *TNX Westlink Report No. 656, September 1, 1993.*

Codeless Coast Guard

For the first time since 1924, the United States Coast Guard has closed down its Morse code operations on 500 kHz. The final CW transmission ended an era at 000Z, July 31, 1993. Coast Guard radio operators first began listening for distress signals on 500 kHz at the turn of the century, and set up its permanent station nearly 70 years ago to monitor the frequency continuously.

Officials say the advent of satellite and digital technology has made Morse code obsolete on the high seas. A misty-eyed Coast Guard radioman tapped out the final 73, saying "We now look forward to serving you on the next generation of communications equipment and systems via the Global Marine Distress and Safety System (GMDSS)." *TNX W5YI Report, Issue 16, August 15, 1993.*

Lunar Repeater

Northern California's Project OSCAR group has proposed installing the first repeater on the moon. Project OSCAR is the group that built and orbited the world's first amateur radio satellite. During recent meetings, the organization has decided to revive "Project Moonray" to take amateur radio into the 21st century.

Moonray is short for Moon Relay, a concept first proposed by W6OLO back in 1965. The idea was to build a repeater that would fit under the seat of the Lunar Rover. But, the project was shelved after Congress cut funding for manned moon missions beyond Apollo 17.

No specific timetable has been offered, although organizers hope to get the project off the ground by the turn of the century—which is only six years and a few months away. *TNX Westlink Report No. 655, August 13, 1993.*

Going Commercial?

We're not talking about the relaxed business communications rules which took effect in September. We're talking about Commercial Radio Operator License examinations. If you've been thinking about sitting for one of these exams, now may be your best chance.

While it may not be common knowledge, many of the questions for the General Radiotelephone Operator License examination are taken verbatim from the Amateur Ad-

vanced and Amateur Extra Class question pools. Those questions are expected to remain in the pool, at least through the summer of 1994—and possibly beyond.

A GROL is required to adjust, maintain, or internally repair transmitters in the aviation, maritime, and international fixed public radio services. The General Radiotelephone Operator License replaced the old First and Second Class Radiotelephone licences back in 1984. It is issued for the lifetime of the holder. *TNX W5YI Report, Issue 17, September 1, 1993.*

Chile Bird

The first Microsat of Chile, named *CEsar-1*, is slated for launch in early 1995, according to the Radio Club Federation in Santiago. The organization will control the new satellite, once it is in orbit.

The Microsat class bird will orbit at an altitude of 900 km. The Radio Club Federation says *CEsar-1* will boost communication between local amateurs and the rest of the world. *TNX Westlink Report No. 656, September 1, 1993.*

Island Quake Mobilizes Hams

The strongest earthquake to shake the world in more than four years rocked the island of Guam on August 8. The temblor struck early Sunday morning, measuring 8.1 on the Richter scale.

More than 130,000 island residents were left without electricity and at least 40 people were injured. Tourists fled from hotels where structural cracks were seen and bridges also suffered damage.

Communication with the northern part of the island became critical due to knocked-out telephone lines and the need for emergency services. Amateur radio and MARS stations were utilized to carry information to and from the disaster area.

Guam is west of the International Date Line, 3,800 miles west of Hawaii, and 1,500 miles south of Japan. There were no reports of injuries or damage at the US military facilities on the 30-mile-long island. *TNX Westlink Report No. 656, September 1, 1993.*

The FARA Project

An economical, easy-to-build, 25 watt 2 meter amplifier.

by James R. Valdes WA1GPO

The Falmouth (Massachusetts) Amateur Radio Association (FARA) is well-known on Cape Cod for its hospitality to newcomers. It is also one of the more active groups in Southeastern Massachusetts supporting two repeaters and a digital Node/LAN. One subgroup of the association is the HACKERS, a group of amateurs who enjoy designing and building their own equipment. When the HACKERS noted that a majority of the new members joining FARA were using 2 meter HTs, we recognized that we might entice some of these new hams into joining this select group of builders by helping them construct a power amplifier for 2 meters. We did this as a group project: Those with tools drilled the holes and those without cleaned and prepped the circuit boards for fabrication or wound the inductors. Those who had experience building gear Elmered those who didn't. All of the participants contributed to the success of this project.

This article describes a 2 meter amplifier capable of running 25-30 watts output. More than 35 amplifiers have been procured at a

cost of less than \$50 each in these quantities.

Photo A shows the final version of the circuit board; the completed amplifier is shown in Photo B. It is designed around one of the newer bipolar RF devices from Motorola, an MRF1946A (Q1). This device compares favorably with many of the RF FETs available as the MRF1946 is capable of developing 10 dB gain at 146 MHz, while the older bipolar devices (the 2N6080 series) produce only about 5.7 dB gain. RF FETs are generally rated at 13 dB gain at 28 volts; in the 12-14 volt range they also yield about 10 dB. The design presented here is unconditionally stable, while FET amplifiers require a bias supply and careful tuning at the higher voltages to maintain stability. The cost of the MRF1946A is only about two-thirds that of the FETs, yielding the most "Bang for the Buck!"

Circuit Description

Motorola produced an application note (RF Device Data, Application AN955) for a 150 mW to 30 watt land mobile VHF amplifier in the 160 MHz range, based on the MRF1946.

This was the starting point for this design.

The schematic diagram is shown in Figure 1. DC voltage into the amplifier is decoupled by C2, C3, L1, C4, C5, and L2. D2 is the reverse polarity protection diode—if the voltage is inadvertently reversed, D2 will limit the reverse voltage to 0.7 volts and fuse F1 will open, protecting the amplifier. The output stripline (Z1) described in the application note was lengthened for operation at 146 MHz and the output capacitor (C10) was empirically adjusted to yield an efficiency in the 70% range, just about what one would expect of a Class-C amplifier. The input circuit was derived from the formulas given in the *RSGB VHF/UHF Manual*. This manual is highly recommended for those interested in VHF/UHF construction. Similar examples of impedance calculations can be found in several editions of *The Radio Amateur's Handbook*. This approach was intended to demonstrate the microstrip vs. lumped constant techniques for impedance matching as one of the more subtle objectives of the HACKERS group is to provide some informal education on radio construction and

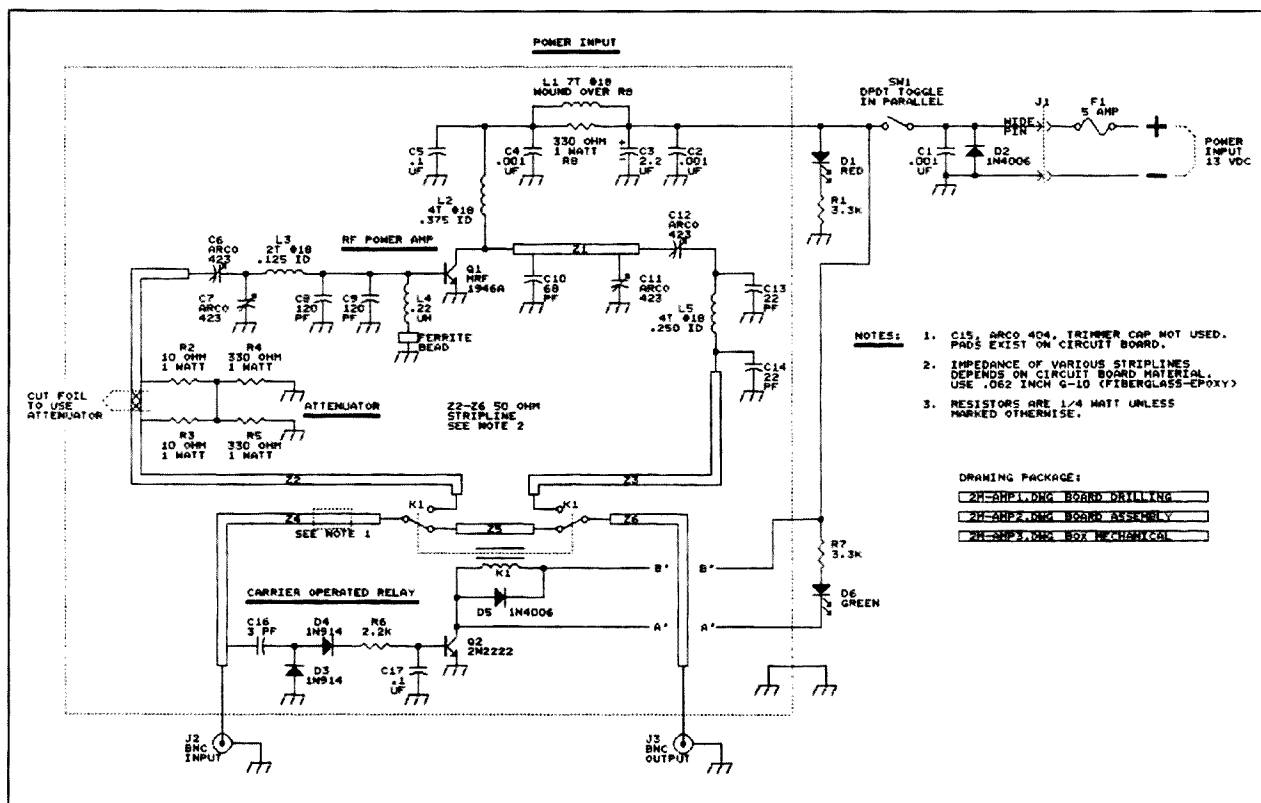

Figure 1. Schematic diagram.

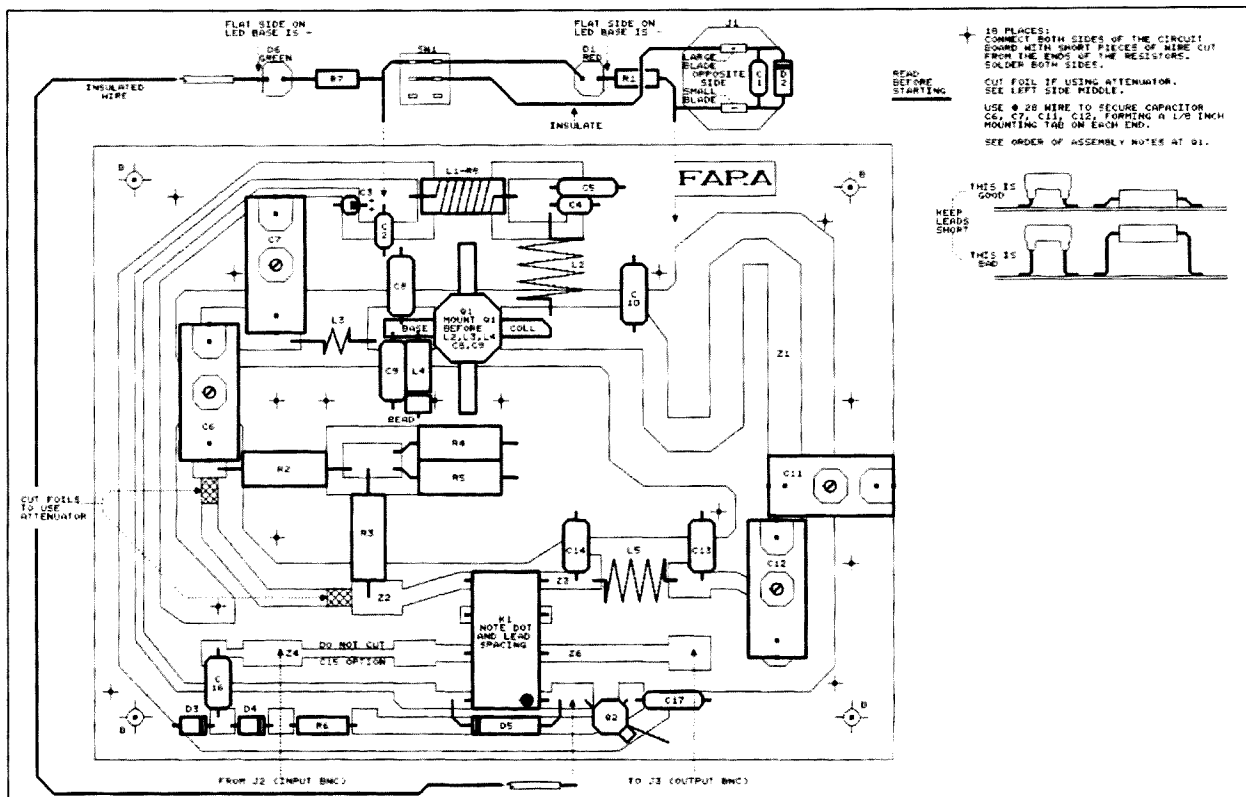

Figure 2. Parts placement diagram.

design practices. A low-pass filter network (C13,C14,L5) is in series with the output to enhance harmonic rejection.

Incorporated into the design is a resistive input attenuator network (R2,R3,R4,R5). The RF power transistor (Q1) is intended to be

driven with 2 to 3 watts input; higher drive levels will not increase the output substantially. Most of the older HTs can drive the amplifier directly, but the new breed of high power, 4 to 7 watt HTs will require the input attenuator. When the attenuator is used, the 50 ohm

microstrip must be isolated at the 10 ohm resistors. Cut the circuit foil at the locations noted on the parts placement diagram, Figure 2. The attenuator represents a nominal 3 dB loss; that is, half of the power is dissipated in the network. In addition to limiting the drive power to a safe level, the attenuator also enhances the stability of the amplifier by isolating the amplifier from the driver. It also presents a nominal 50 ohm resistive load to both units. If the attenuator is not required, the network consisting of resistors R2,R3,R4,R5 should be omitted.

An RF-actuated T/R relay (K1) has been incorporated into the amplifier. RF on the input is sampled by C16, rectified and limited by D3, D4, R6, and C17 to turn on Q2, which pulls in the relay. We considered using solid-state T/R switching. However, relay switching has the advantage that the amplifier can be turned off when it is not required. Conversely, diode-switched amplifiers must be powered at all times. This is in keeping with the spirit of the FCC regulations that require radio amateurs to use "the minimum power necessary to carry out the desired communications." Relay switching also results in a more compact, easier-to-duplicate amplifier. The relay specified in the Parts List is a small, open-frame style. Its performance is adequate for 2 meters.

Should you be a "purist," you can compensate for the inductance of the relay by installing a variable capacitor (C15) in series with the input to the relay, as noted on the parts placement diagram. This capacitor was

Photo A. Printed circuit assembly.

Figure 3. Printed circuit foil pattern (component side). Metal is shown in white, black areas are the etched surfaces.

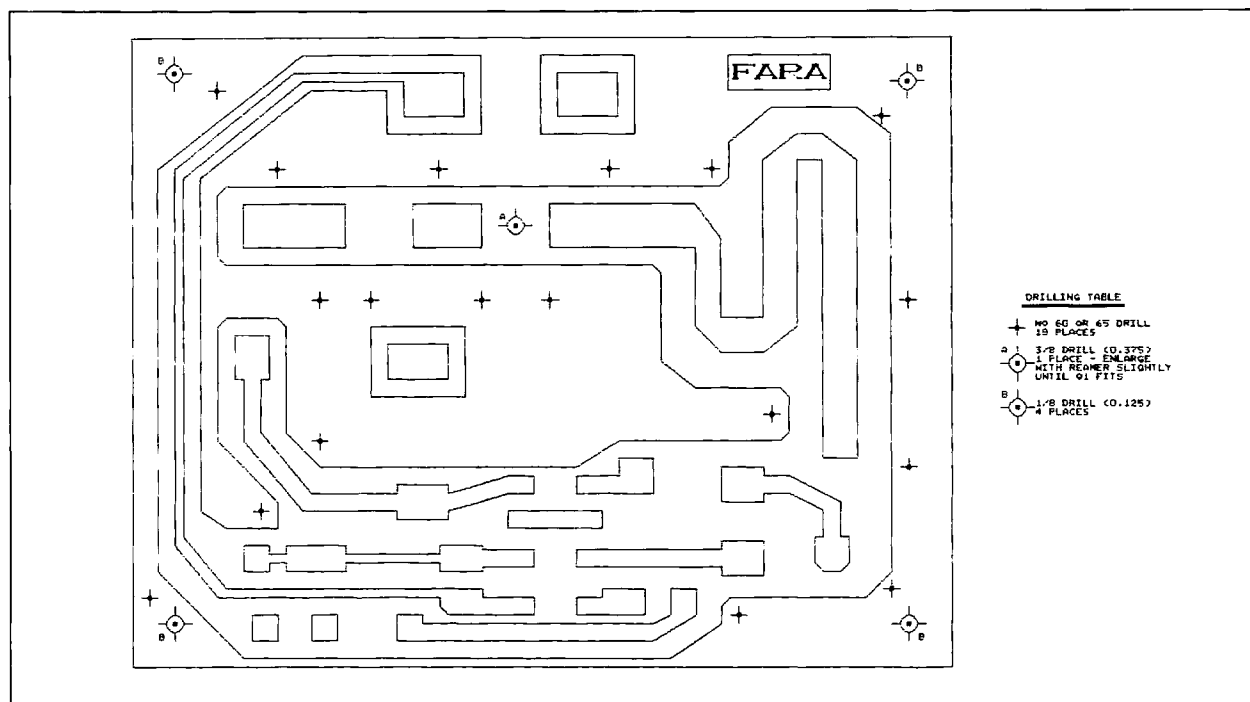

Figure 4. Drilling template.

not used on our production run. All of the input and output foil runs are constructed of 50 ohm microstrip (Z2-Z6) etched into the circuit board. The circuit can be modified for solid-state T/R switching. A PIN Diode T/R switch may be a better choice for packet operations, which require high speed switching. Several articles (including "A 2 Meter FET Amplifier for Your Handheld" by John Cunningham AA4AW, 73 *Amateur Radio Today*,

Oct. 1992, p.20) and the ARRL handbooks contain examples of diode switching.

A word of caution concerning the circuit board. It must be constructed of 1/16", double-sided, G-10 glass-epoxy board with 2 or 3 oz. copper. A full-size negative for the circuit board is provided (see Figure 3). The side of the board opposite the stripline remains a solid copper ground plane as it is not etched. Failure to reproduce the board exactly as

shown, with the materials specified, will dramatically affect the performance of the amplifier because the dimensions for the striplines are critical.

Low impedance grounds are crucial to the operation of the amplifier. A number of holes (18) must be drilled through the board (see Figure 4). No. 20 wire is inserted through these holes and soldered to electrically tie both sides of the circuit board together at the

Photo B. Completed amplifier.

Photo C. Interior chassis view.

points indicated. Some flux may enhance the solderability on the ground plane side of the circuit board. Be sure to use only rosin core-solder!

Construction

Photo C is a view of the amplifier mounted in the suggested enclosure; it should be noted that the circuit board shown in this view is one of the earlier prototypes. It's a good idea to use the circuit board as a template to mark the case for the mounting holes before soldering the components to the board.

The MRF1946A utilizes an 8-32 stud for the heat sink and mounts with a single hole through the circuit board. Take care when mounting the device to insure that no strain is placed on the transistor's leads when it is sol-

dered. It must fit flush on the circuit board. A little thermal heat-sink compound on the flange of the transistor mounting stud is recommended to maximize heat transfer. Careful—don't get this stuff on your clothes because you'll never get it off! The circuit board mounts to the case with 4-40 hardware. Use 4-40 nuts under the circuit board corners to space the transistor mounting stud correctly. The heat sink (aluminum channel stock) and the chassis details are given in Figure 5. I prefer BNC connectors for the RF connections as they mount with a single hole and perform better than UHF connectors at the frequencies of interest. The LEDs, switches, and reverse polarity protection diode are wired from the case-mounted components to the circuit board. Don't forget to install the

fuse in series with the DC power plug.

Attention should be paid to standard VHF construction practices. Some pitfalls to be aware of when constructing the amplifier are:

- Components should be mounted flush to the board; i.e., the fixed capacitors should be mounted as close to the foil as possible. Bend the leads perpendicular to the body after removing any enamel from the leads, then solder the components to the board with the minimum lead length possible.

- The wires through the board should be bent into a "Z" shape after insertion through the board prior to soldering.

- Periodically, the flux should be removed from the board during the construction process. Pay particular attention to the striplines

Continued on page 18

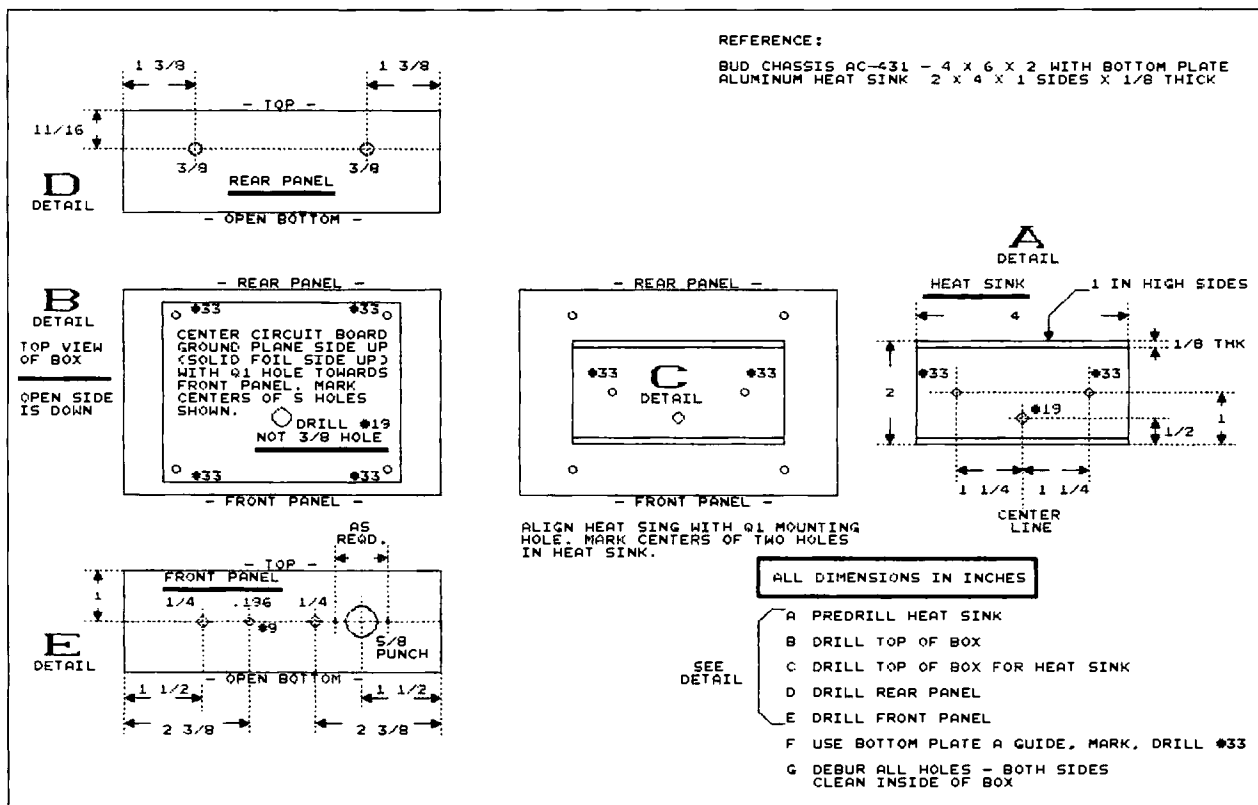

Figure 5. Chassis details.

The FARA Project

Continued from page 16

and the transistor mounting tabs. These areas must be *clean*. If not, you may have some difficulties when tuning the amplifier.

•With the large ground plane of the circuit board you must be careful that there are no cold solder joints. The joints should be shiny and should puddle well after soldering; they should not look crystalline or like a blob. Good soldering techniques are crucial to the performance of the amplifier.

Tune Up

The amplifier is quite easy to tune: Only a DC ammeter (5A full-scale), a 12-14 volt 5A power supply, a suitable RF power meter (50 watts full-scale), and dummy load are required. Initially the amplifier should be tuned at 12 volts with an input power of no more than 1 watt. Until the amplifier is completely tuned, RF should be applied to the input for no more than three to five seconds at any one time. Prior to mounting the amplifier in the enclosure you should rough-tune the amplifier. Be sure the transistor is mounted to the heat sink when tuning.

Tune the amplifier as follows:

1. Apply 12 volts, with the ammeter in series with the positive lead. There should be no current indicated on the meter. Set the power switch to OFF, then peak the relay compensating capacitor (C15), if installed, for maximum output in the bypass mode.

2. Turn the power switch ON and apply 1 watt (as noted). The relay should pull in. Tune all capacitors (C6,C7,C11,C12) for maximum output. Do not tune the relay compensating capacitor (C15) at this time.

3. Set the power supply voltage to 14 volts and increase the drive to the maximum 2 to 3 watts input at the transistor. 4 to 7 watts *maximum* at the input of the amplifier, provided the attenuator is in place.

4. Again, tune the capacitors for maximum output.

Pay attention to the current being drawn. You will notice a substantial increase in current when the series output capacitor (C12) is off resonance. Tune the amplifier for the best efficiency; that is, tune for the highest power output consistent with the minimum current being drawn. Nominal values are about 3.5 amperes at 28 watts output.

Results

To date, the 30 amplifiers we have built have been a great success! The primary goal of the Hackers Group—that of introducing new hams to the construction side of the hobby—was met. They were able to construct a useful piece of equipment at a nominal cost and they enjoyed doing it.

This was a group project and everyone who participated contributed to its success. I would personally like to acknowledge the support of four individuals: Don NIJCT, who helped coordinate the project and who prodded me into designing the unit; Bob WIHWU, whose expertise in circuit board fabrication was crucial to the success of the project; Harry W2RKB, who helped with the circuit boards and tune-up; and, last but not least, John NILO, who provided the CAD drawings.

Ideal for SKYWARN and A.R.E.S.

Now you can do something about the weather

The ULTIMETER® II Home Weather Station protects your equipment, helps you alert others to dangerous weather extremes

This ultra-reliable Weather Station is your first alert to changing local weather conditions, gives you up-to-the-second data to transmit on SKYWARN and A.R.E.S. networks.

The ULTIMETER II tells you when high winds threaten so you can crank down your tower and safeguard other equipment. You get over 20 weather functions vital to ham and other homeowners, including high/low temperature readings with pre-set alarms that help you plan your day, guard against frostbite, protect plants and people.

The ULTIMETER II's unique low-impedance wind sensor (patents pending) resists RFI, improves reliability and shows speed and direction simultaneously. Comes with 40 ft. cable.

Improved VOX Mobile Extender

Give your handheld the power of a mobile.

by John Neeley K6YDW

This article improves upon my original "Mobile Extender Using VOX Control" project, which first appeared in the December 1987 issue of 73 (pages 44-45). While the original project worked OK—it had a few drawbacks. For one thing, it utilized parts which are difficult to impossible to find today. This new and improved version solves that problem and goes a step further. It uses commonly available parts but also works quite a bit better. This version also eliminates the intermittent reception problem which cropped up in the original, thereby improving communications.

Why Build the Extender?

This project can be invaluable at parades, public events, and especially in search and rescue work. When the extender is operating, you can leave your vehicle and still be in contact with others on the repeater channel via the extender. This is important if you can't access the local repeater via your hand-

ie-talkie in your portable location. Using the extender allows you to use the higher power mobile radio in your vehicle to access the repeater. You will also have the advantage of a gain mobile antenna over a rubber duckie.

Circuit Description

In the original circuit, the speaker output of the receiver went to an audio transformer, with a diode in series on the secondary, which produced a DC voltage to drive the input of an LM3900 Norton op amp IC. This arrangement was satisfactory, but at times would become intermittent due to voltage changes on the input to the LM3900. The improved version, shown in Figure 1, is not as dependent on varying input voltages, thereby making the circuit more reliable. Voice modulation is no longer required to activate the circuit. Instead, it will activate upon hearing the receiver noise, when the squelch is opened.

Two identical circuits, using a single

LM386 400 mW audio amplifier IC in each channel, instead of a single LM-3900 IC, are built to make the extender. The 1RF511 power MOSFET is available from Radio Shack and other suppliers. If a relay output is desired, the 1RF511 can be replaced by an NPN transistor. The 1RF511 has very low on-state resistance, combined with high transconductance, and the capability of sinking 3 amperes.

When the gate of the MOSFET is driven high, the drain goes low, which will key the T/R relay in the transceiver. The only voltage on the drain is supplied by the relay of the radio. Parallel to the drain output of the MOSFET is an over-voltage protection circuit consisting of a zener diode (Z1, Z2), and a 0.01 μ F disc capacitor (C7, C16) to prevent voltage spikes from destroying the MOSFET.

Diodes (D1, D2) rectify the output voltage of the LM386 IC from AC to DC, to operate the MOSFET keying transistor (or NPN/re-

lay configuration). The LED indicators are optional, but they do give a visual indication as to which channel is active. I use a red LED for "CHNL A," green for "CHNL B," and yellow for POWER ON.

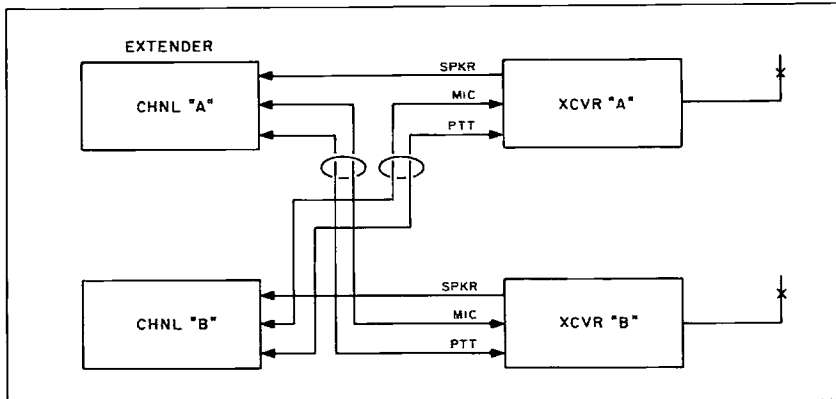

Figure 3. It's easy to hook up the Extender to your radios.

Transmit Audio Circuit

The transmit audio section is identical to the original article. The speaker output of one receiver goes through a 470k ohm resistor (R15, R17), to a 0.1 μF capacitor (C17, C18), then terminates at the microphone input of the other transmitter. The values of the resistor/capacitor network may vary, depending on your radio, but the device has been found to work with several different types. It is suggested that the network be placed directly at the I/O jacks (J1, J2), instead of on the PC board. See Figure 2.

Wiring It Up

Figure 3, the wiring diagram, shows how simple it is to hook it up to your radios.

XCVR "A" speaker output goes to CHNL "A" input; CHNL "A" output (MIC/PTT) goes to XCVR "B" microphone/PTT jack (reverse for the other channel). XCVR "A" should be on your 2 meter repeater channel, or can be on simplex. XCVR "B" can be on your 2 meter repeater channel, or can be on simplex. XCVR "B" can be on any simplex channel, preferably on either 220 or 440 MHz, to prevent desense.

Operation

To use the unit, plug in the appropriate cables to the transceivers. The input/output jacks (J1, J2) of the extender are wired the same, so all you need to make up are the cable connectors going to your transceivers. Refer to your radio's manual for correct wiring and types of connectors required.

Select XCVR "A" to an active repeater channel; set the volume control on the receiver to about halfway on each radio for initial tests. Monitor on another receiver: set to XCVR "B" transmit frequency, and adjust the 25k pot (R1) to where the circuit keys XCVR "B."

Now adjust the receiver volume to where the audio has good quality. Again, these values may need to be changed to fit your radio, but they should be correct for most units. Now you can do XCVR "B," which is the same procedure. The 5-pin DIN jack wiring is shown in Figure 2.

Construction

The circuit can be constructed on a printed circuit board from FAR Circuits (see note at the end of the Parts List). Place the board, along with the associated switches, LEDs and jacks, in a metal box of your choice and mount it in a suitable location near

TELEPHONE LINE TEST HANDSET

AT&T # 206A2

These rugged line test handsets were originally designed for use with AT&T's "Craft Access" computer. They can be used like any other line test handset, but they have special features which may or may not be useful. In addition to the touch-tone keypad, talk/monitor switch, alligator clip leads, 4 conductor modular jack and tool belt clip, these units have a LCD screen and function button/ joystick for use with AT&T's "Craft Access" computer. For the average user, the extra features mainly allow you to adjust the volume and program in phone numbers. The main drawback to these units is that they contain batteries that require recharging, and the test set should be recharged when not in use. The size of the unit is 12.5" long X 4.5" wide. Brand new, in the box. They include 2 ni-cad battery packs, a charger and instructions.

The Solar Control-ar

A solar panel charge controller for all seasons.

by Joel R. Donaldson WB5PPV

My home is on wheels. My ham shack is on wheels. I live in an old motor home, often staying for months in remote areas that lack any AC power. I'm no rugged old geezer when it comes to creature comforts, however. My idea of roughing it is having to warm something up on the gas stove, instead of cauterizing it in the microwave. Given this affinity for modern gadgets (and my inability to convert my Yaesu to operate on propane gas), I've been forced to come up with alternate ways of obtaining electricity for my comfort and pleasure. My RV came equipped with a big, stupid Onan generator. It uses a little less than a gallon of fuel for every hour of operation, regardless of whether or not it's powering anything. It's cranky to start on cold mornings. It interferes with my TV and HF reception. During weekly skeds on 20 meters, I find myself shouting into the microphone to make myself heard over it. It hunts, surges, and revs for no apparent reason. It sets off my smoke alarms, even when it isn't actually on fire. In short, it stinks. Literally.

After several months of power generation aggravation, I bought a combination inverter/battery charger so I wouldn't have to run the generator all the time. It's coolness incar-

nate! It's 85 to 90 percent efficient, and completely silent. You have 120 volts AC whenever you want, with the flick of a switch. Yep, I'll only have to run the generator for several hours a day now, just long enough to recharge the RV batteries, right? Well, not exactly. As it turns out, you can only rapid-charge a lead-acid battery up to about 75 percent of its total capacity. After that, the last 25 percent takes a long time, regardless of how big your battery charger is. Try to save some time by really cranking up the charge current and all you get is a boiling battery with melted plates. Great. Now I can run the generator for two hours to build up the bulk of the battery charge, and then run it for another four or five hours just to top it off. Or I can shut it down after several hours and live with undercharged batteries, right?

Well, not exactly. As it turns out, an excellent method for prematurely ruining a lead-acid battery is to consistently undercharge it. In the process of discharging, the lead plates in a battery are converted to lead sulfate. If the battery is promptly and fully recharged, this sulphation is almost completely driven back into solution, leaving the plates essentially unchanged. However, if the battery is

not completely recharged, the sulphation hardens into a form that is eventually not removable with any amount of recharge. When this happens, there is less plate area available in which chemical reactions can occur, and the battery permanently loses capacity. The process continues until the battery can't hold any charge at all, and . . . it's toss time!

So much for quick charges with the generator. I really need a scheme that provides a gentle, continuous low-current battery charge over long periods of time, say maybe five to eight hours, something that is quiet, doesn't stink or guzzle gasoline, is easy to maintain, and doesn't need to be attended while it's doing its thing.

Well, you know what the answer had to be.

Shortly after I mounted four 53 watt Siemens solar panels on the roof of the RV, I began to search for a good charge controller. I looked at both the store-bought and the roll-your-own types. Most charge controllers don't exactly teeter on the leading edge of technology, but the way some of them work is still kind of neat. Unfortunately, all of them I looked at suffered from at least one of the following maladies:

- 1. They were expensive.
- 2. They were either incapable of controlling a large number of solar panels (typically being limited to a maximum of 8 to 15 amps), or they wouldn't work with anything less than a large number of panels.
- 3. They were inefficient, with a significant percentage of the panel array's total power output being wasted as heat within the charge controller.
- 4. They lacked truly useful metering capabilities.
- 5. They lacked sufficient adjustability, or the adjustments wouldn't stay put.
- 6. They couldn't be manually bypassed in case of failure or for routine battery equalization.
- 7. They had little (if any) immunity to strong RF fields.

With these problems in mind, I set out to design my own controller. In addition to avoiding everyone else's pitfalls, I had to make the final design simple and use readily-available parts. Because several hundred to several thousand amp-hours of storage batteries represent a considerable investment, the design also had to be reliable. No one wants to leave their house, RV or repeater site unattended for an extended period, only to later discover that the controller has failed in the "on" position, indefinitely subjecting their batteries, inverter, radios and other appliances to the full 18 to 20 volts produced by their solar panels. Or, just as bad, failed in the "off" position, with the batteries totally Tango Uniform.

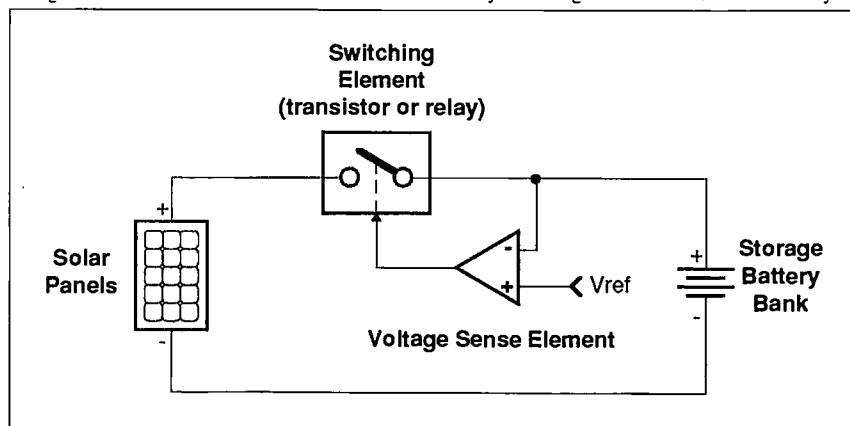

Figure 1. Series control scheme.

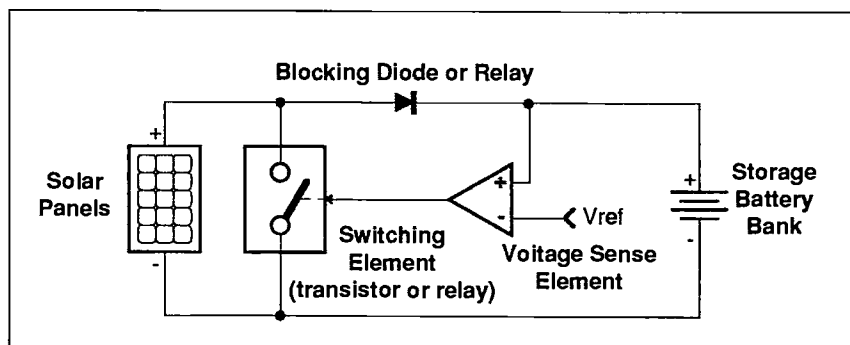

Figure 2. Shunt control scheme.

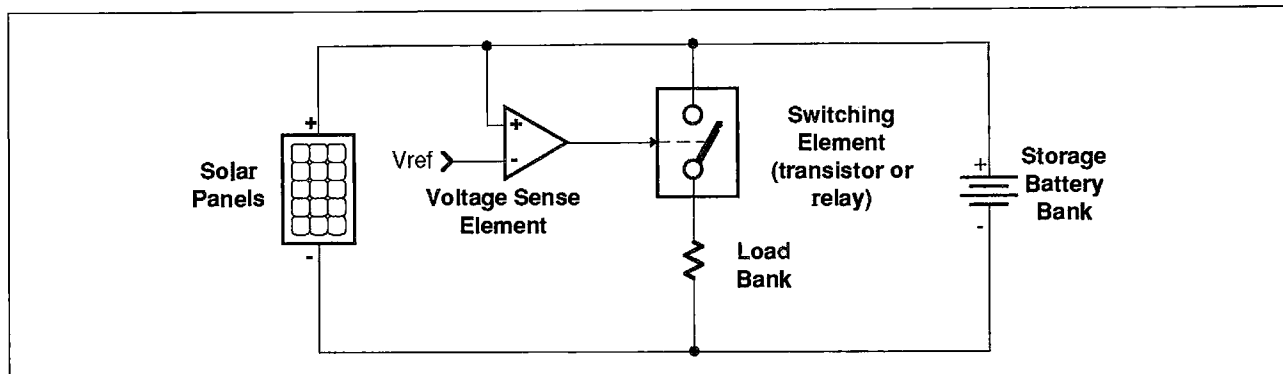

Figure 3. Diversion control scheme.

Series Control Scheme

In my survey of what's already out there, I found that one of three different techniques may be used in the typical charge controller to limit the solar panel's output upon completion of battery charge. Each technique has its own advantages and disadvantages.

See Figure 1. *The series-regulated* approach uses a switch in series (surprise!) with the solar panel output to disconnect the solar panels from the batteries as soon as the desired level of charge is reached. The biggest advantage of this scheme is probably its simplicity. As with the other approaches, the actual switch may be a relay contact, or one or more power transistors. The relay-types cycle on and off at long intervals (from several min-

utes to several hours, typically), while designs that use power transistors may cycle at rates up to several tens of kHz, à la Pulse Width Modulation.

Shunt Control Scheme

The *shunt-regulated* approach shorts out the solar panels as soon as the batteries are charged. Solar panels, being essentially constant-current sources, are in no manner harmed by being shorted indefinitely. The output voltage just drops to almost nothing as the current increases only very slightly above its normal value. With a really low-impedance shunt switch, the shorted-out power dissipation can be held to very low levels. Note that a blocking diode or secondary switch is used

in conjunction with the shunt switch in order to avoid also shorting out the connected batteries (definitely something to avoid!). Although the additional diode or switch complicates this approach somewhat, it still has the advantage of being a relatively simple scheme to implement.

Diversion Control Scheme

Unlike the previous techniques, the diversion-regulated approach doesn't attempt to prevent energy from reaching the battery as it reaches full charge, but instead siphons off excess energy so as to maintain the desired battery voltage. As the batteries top off, the controller automatically switches a load bank across them, so as to keep the voltage from

AT LAST!

NEW REV. 3.0 SOFTWARE UPGRADE for the NIR-10 IS HERE!!!

The **NEW** Rev. 3.0 PROM sets are now available from JPS Communications. This update adds a new **PEAK** function to the unit to provide an additional method of noise removal to the NIR mode. **PEAK** may be used by itself or along with the NIR mode to effectively reduce or eliminate white/pink noise and other similar types. This markedly improves the NIR-10 white noise reduction without the annoying audio "surging" present in other peaking-type noise reducers. **PEAK** works by dynamically peaking all coherent signals in the audio passband, reducing the effective bandwidth to the minimum required to pass

the information. **NOTCH** performance has also been enhanced.

The upgrade consists of two plug-in PROMS to replace those presently in your unit. Price of the upgrade is \$25.00. If you are a NIR-10 owner and did not receive a card from JPS telling you of the upgrade, please send us your name, call sign (if applicable), address, telephone number, and **NIR-10** Serial Number, along with VISA, Mastercard, check or money order if you wish to receive the upgrade.

All units now at dealers and from the factory are Rev. 3.0!

climbing any higher. As the load bank starts to overwhelm the output from the solar panels, the battery voltage begins to drop, eventually reaching a point at which the load bank is automatically disconnected. This connection-disconnection process continues as long as the solar panels are producing a surplus of power, thereby preventing overcharge. A big advantage of these controllers is that they don't care what sort of power source is actually doing the battery charging; all they are concerned with is keeping the battery voltage from exceeding a set value. This makes them useful in situations where solar battery charging is supplemented by other charging sources (like wind chargers or water turbines). No matter how many different charging sources you add to a battery bank, just one diversion regulator

will control them all, as long as the combined current output from all sources does not exceed that of the regulator or the load bank attached to it. The biggest disadvantage of this scheme is probably the load bank requirement, which forces you to figure out what you are going to do with any surplus power produced by the system.

One nice thing about all three of these techniques is that once the batteries have reached a state of complete charge, the excess solar energy does not necessarily have to be discarded but can be instead used to power other lower-priority loads. In the case of the series and shunt regulation schemes, all you have to do is substitute a power diversion switch for the existing disconnecting or shorting switch. For diversion regulation systems you just con-

nect your alternate load in place of the controller's load bank. Any electrical load will suffice, so long as it is tolerant of frequent disconnects from power. In the case of diversion regulation, the load must also be ever-present, and must be large enough to be capable of swamping the output of the solar panels on even the sunniest of days. Good potential candidates for load banks would include water pumps (you can always stand a little more water in the stock tank as soon as the batteries finish charging), cooling fans (keep the wife and the chicken coop cool) and, in larger solar installations, hot water pre-heating or electrical generation of hydrogen gas (for later use as a fuel).

Note that all three of these regulation techniques are typically implemented with saturated on-off switching. Theoretically, you could incrementally adjust the amount of voltage or current being produced by your panels as the battery charge increased, using pass transistors biased in a linear mode. The biggest practical disadvantage to this technique probably lies in the tremendous amount of heat that would be generated by the pass transistors at any point between saturation and full cut-off. All that heat would have to be dissipated somewhere, and at the very least would result in increased size and cost, due to a rather herky heat sink! So, linear regulation is probably not as well suited to the constant-current nature of solar cells as it is to power sources with essentially unlimited supply currents (like batteries and AC mains). The sole

exception might be in controllers for very small solar arrays, where heat dissipation could be more easily managed.

Anyway, this survey provided a good starting point for my own design. For the switching element, I considered using relays, power BJTs, and power FETs. A power relay looked good from a cost standpoint (you can buy a fog lamp relay at Wal-Mart for less than \$4, and you don't need a heat sink), but the reliability of the contacts would always be suspect. High power FETs are easier to use than BJTs, and are very reasonably priced, so they looked like the best choice. As for the actual circuit configuration, I considered several factors important.

First, the use of a transistor in a series switch arrangement would mean that some power would be wasted in the voltage drop across the transistor when the battery was being charged. This would reduce the efficiency of the charge controller somewhat. Likewise, the use of a shunt switch arrangement would mean that some power would be wasted in the voltage drop across the blocking diode.

Second, the power being dissipated across these components (in either configuration) is significant for rather long periods of time (whenever the sun is shining and the batteries are not fully charged), which could shorten their life expectancy. A diversion regulation scheme avoids these two problems because no switching or blocking device is employed between the solar panels and the batteries, and the diversion load switching device is only operated for brief periods *after* the battery has reached full charge. This implies good efficiency and reliability. Since no blocking diode or series switch is used, there will be some loss of efficiency with this arrangement, due to nighttime solar panel reverse leakage current (typically 15 mA per 50 watt panel), but this is more than offset by the higher daytime efficiency. So there you have it—an FET-switched diversion regulator it is!

From that point on, the design was pretty straightforward. In referring to the schematic, you'll see that U2 compares the battery voltage with a reference developed by U1, and turns on Q1 as soon as the battery voltage exceeds the level set with R12. Q1 in turn grounds the alternate load (R2), which swamps the output current being produced by the solar panels. Note that since the

LM317LZ can't regulate a voltage that approaches its input value (e.g., the battery voltage), it is instead set to a lower reference voltage (approximately 6.5 volts). The R9/R11/R12 pair scale the battery voltage down to a value roughly comparable to this reference. Since the 741 is incapable of output voltage swings completely to ground, U2 compares the battery voltage with a reference developed by U1, and turns on Q1 as soon as the battery voltage exceeds the level set with R12. Q1 in turn grounds the alternate load (R2), which swamps the output current being produced by the solar panels. Note that since the

the controller's resistance to mechanical vibration, a multi-turn trimmer is used for R12 (10 to 15 turns works nicely). The voltage difference between termination and resumption of battery charging (e.g., the charger's hysteresis) is adjustable via pot R13.

In addition to driving Q1, U1 also directly drives the "BATTERY CHARGED" indicator LED. Note that unlike some other charge controller designs, this LED is not lit until *after* the battery reaches full charge.

A single International Rectifier 50 amp

Figure 5. PC board foil pattern (100%) and parts placement diagram (200%).

power FET is specified in the Parts List; it is available from Digi-Key (701 Brooks Ave. South, P.O. Box 677, Thief River Falls MN 56701-0677; telephone 1-800-DIGI-KEY for a free catalog) for around four dollars. Other smaller FETs can be substituted for lower power handling requirements, or several FETs can be paralleled in extremely large installations. I like using a well-oversized FET, for reliability reasons.

The metering circuit I chose measures the amount of current produced by the solar panels, and also determines battery voltage. The vast majority of the charging current is borne by R1, while a small portion of it is diverted through the meter. Since the meter uses a 1 mA movement, the voltage drop across R1 never exceeds 50 mV, thereby minimizing power losses and heat dissipation. Physically, R2 consists of a small coil of 14-gauge household wire, the exact length of which is determined by the desired full-scale reading of the meter. I set mine up for a full-scale current of 14 amps, but Table 1 lists the appropriate lengths for some other full-scale values. I chose 14-gauge because it is readily available in most hardware stores. Solid is preferred over stranded.

To read battery voltage, R4, R5, R6, CR5 and CR6 are used in a voltage-scaling circuit that allows the meter to read from approximately 10 volts no-scale to 16.5 volts full-scale. The expanded voltage scale is important because there is typically less than 1 volt

Figure 6. The precise value for R1 can be calculated after finding the meter's resistance value.

of difference between the output of a fully-charged and a fully-discharged lead-acid battery. Any small variations within that 1 volt range would be difficult to read on an analog meter, unless the meter scale was expanded to remove the useless 0 to 10 volt range of readings. (Whether your battery reads 10 volts or something less than 10 volts is immaterial; in either case you have a damn dead battery on your hands!) On the top end of the scale, the normal charge-cutoff voltage for a lead-acid battery can range as high as 14.8 volts, with equalization being safely performed at up to 16.5 volts (see the sidebar on battery charging). This value sets the desired upper range of measurement. For temperature stability, current is always applied to CR6. This repre-

sents a small continuous battery load (less than 20 mA under most conditions), but buys some improvement in meter accuracy.

For ease of construction, a printed circuit board layout has been provided. Almost all of the components carrying low currents mount on it, while the components requiring heavy-gauge wire mount in what ever type of enclosure you desire. I mounted mine in a wall paneling cutout, using the aluminum cover from a bakelite experimenter's box as the front panel. These covers are available without the rest of the box from Digi-Key for under \$2. Make sure that the PC board is mounted so that R12 and R13 can be easily adjusted with everything buttoned together.

If a "live" diversion load will not be used

CIRCLE 164 ON READER SERVICE CARD

in your installation, R2 can consist of 12 volt light bulbs (headlamps for high current applications; #1141 bulbs for smaller installations), or power resistors. I recommend that the load be spread among several individual resistors or bulbs so that if one burns out, the controller will still function (although at some reduction in overcharge protection). Also, if bulbs are used, be sure to pick a bulb with long life (e.g., 1,000 hours for the #1141, versus only 200 hours for the similar-appearing #1156 bulb). Using 24 volt bulbs in a 12 volt system will also greatly extend reliability, although more bulbs will be required. High-power load resistors can be easily built from scratch with nichrome heating wire (available at most hardware stores), and mounted in ventilated metal boxes, tin cans, etc.

To calibrate the meter for battery voltage, set R5 and R13 at the middle of their ranges, and switch S2 to the voltage scale. Disconnect any alternate load. Apply +10 VDC to the battery terminals and allow CR6 to warm up for a few minutes before proceeding. Adjust R5 to just below the point at which some meter deflection starts to occur. Gradually increase the voltage at the battery terminals, noting and recording the resulting meter readings. (These readings can be used later in relabeling the meter face, if desired). As you increase the voltage, verify that the meter pegs out at a little over 16.5 volts of input. Next, set the input voltage to the desired battery charge cut-off value, and adjust R12 until the

BATTERY CHARGED indicator lights up. There are no adjustments for calibrating the current scale; the current readings can be read off an ammeter connected in series with the positive battery wire, once the controller is installed and hooked up to the panels and batteries. Again, the current readings can be recorded for later use in relabeling the meter face.

During installation, I recommend providing fusing between the charge controller and the batteries, located as close to the batteries as possible. In some larger solar installations, you might want to consider remote-mounting the meter and PC board, if it will save you any appreciable length of heavy-gauge (bulky and expensive!) wire. If going that route, simply mount the PC board, S1, S2, F1, and the meter in a box located for viewing convenience, and mount everything else somewhere directly between the solar panels and the batteries. Small-gauge wiring (e.g., telephone cable) can then be used to connect the two boxes.

After the controller has been installed, readjust R12 for proper charge cut-off voltage. The difference between charge cut-off and turn-on voltage is set with R13, and will vary with battery size and loading. Normally, R13 should be adjusted so that CR4 does not cycle more than several times a second under light battery loads, but should never fail to resume charging when battery voltage drops below approximately 13 volts. There is some in-

teraction between the settings for R12 and R13, so several readjustments may be necessary to get the desired charge cut-off and resumption voltages.

The controller is heavily bypassed for RF interference rejection. For best RF rejection, it is suggested that separate wiring be used to connect the radio(s) to the batteries. A metal enclosure for the controller also helps and, finally, a 100 μ H RF choke can be added in series with the fuseholder in particularly stubborn situations.

If you have access to a computer, laser printer, and drawing or drafting software, you can relabel the meter face in a very professional manner. First, recreate the physical dimensions and markings of the old meter face with your drawing program. Next, substitute your recorded voltage and current readings for those of the existing meter face, in the corresponding positions on the meter scale. Finally, use your laser printer to print the new meter face on large adhesive-backed label paper (Avery 5165 or equivalent), and stick the new face over the old one. Very spiffed!

In conclusion, I think you'll find that this controller is the best battery banger for your buck. It's efficient, reliable, and has all the useful tweaks. Whether you're building a mansion in the middle of nowhere, sticking a TNC on top of the local mole hill, or just need a little something to keep your Argonaut's trolling motor battery from boiling dry, this little baby will do the job.

A NO-RADIAL VERTICAL THAT COVERS 80 OR 75 METERS?

THERE'S ONE NOW!

No, we won't insult your intelligence by telling you that it's a "halfwave" or that ANY vertical will operate more efficiently without a good radial system than with one; it certainly won't! If you want expensive fairy tales talk to our competitors! If, however, you've no room for even the smallest radial system just install the most efficient multiband vertical in the business, the HF9V-X, over our counterpoise kit. You'll not only save a tidy sum but you'll work DX that the shorter and more lossy no-radial "halfwaves" can't touch because both the HF6V-X and HF9V-X use longer active element lengths for higher radiation resistance and greater efficiency on more bands than any of the so-called halfwaves. Ask for our free brochure for complete specs on all Butternut models and receive technical note DLS-1 "Dirty Little Secrets from the Antenna Designer's Notebook" that shows you how to calculate the probable efficiency of any vertical antenna using the manufacturer's own specs so you won't have to learn the truth the hard way!

Model HF9V-X (shown to the left) for 80/75, 40, 30, 20, 17, 15, 12, 10 and 6 meters.

Model CPX counterpoise kit for Butternut models HF9V-X, HF6V, and HF6V-X; substitutes for ground or elevated radials. Self-supporting tubing bolts onto base of antenna. Mast not provided.

BUTTERNUT ELECTRONICS CO.
 P.O. Box 1234, Olmito, TX 78575 (210) 350-5711

While most other components in an alternate energy system are virtually indestructible and maintenance-free (with the possible exception of wind chargers and water turbines), the selection and maintenance of electric storage batteries can make or break the entire installation. Make your battery selection carefully and maintain it properly and it will serve you well for years. Make the wrong choice or neglect your investment and you will soon have another opportunity to make a wiser battery purchase!

Storage batteries used in most solar power applications are either lead-acid or NiCd. Lead-acid batteries can be cheaply purchased new almost anywhere, while NiCd cells are generally available only as surplus. The big advantages lead-acid cells have over NiCds are that they are more efficient to recharge (only 15 to 20 percent of the charging energy is lost, as compared to 25 to 35 percent for NiCds), they offer better voltage regulation under load, and they are usually cheaper than surplus NiCds. On the other hand, NiCds are much more tolerant of extreme discharges, and are not as prone to permanent damage due to repeated undercharge or long-term storage in a discharged state. Since the vast majority of solar installations use lead-acid batteries, most the following information will center around them.

Some Battery Basics

The lead-acid battery types that are most common in solar applications are all of deep-cycle design. This is significant, because a deep-cycle design stands up to repeated heavy discharge-recharge usage much better than a battery of ordinary automotive design does. An automotive battery

is designed to deliver very large bursts of current for short periods (when starting a car), and then is immediately recharged (by the car's alternator). Most solar power applications require the battery to provide lesser amounts of current, but provide it for extended lengths of time before receiving any recharge. An automotive battery will lose a significant percentage of its full storage capacity after being heavily discharged just one time. It will typically lose 50 percent of its capacity after 20 such discharge-recharge cycles. (For our purposes, a heavy discharge is one that removes all but 20 percent of the battery's original full charge). By contrast, even the lightest duty deep-cycle battery will typically tolerate 200 to 300 such discharge-recharge cycles before reaching a similar state; some of the heavier deep-cycle designs can exceed 10,000 such cycles. It is a common mistake to purchase the "biggest batteries you can get" for a new solar installation, usually meaning size 4D or 8D truck/tractor batteries (which are conventional automotive designs). Regardless of how "heavy duty" a battery is claimed to be, if it isn't a deep-cycle design, it won't last very long in most solar applications.

The maximum storage capacity of a deep-cycle lead-acid battery is usually specified either in amp-hours or in minutes of reserve capacity. The amp-hour value refers to the number of amps a battery will deliver over a specified period of time (generally implied to be 20 hours, if not specifically stated), before the battery has discharged to a useless level (around 10.5 volts). The reserve capacity value specifies the number of continuous minutes the battery can last while delivering 25 amps, before dropping

to this same 10.5 volts. As a rule of thumb, for the smaller batteries, you can multiply the number of reserve minutes directly by 0.6 to arrive at an approximate equivalent amp-hour rating for the battery. Therefore, a 50 amp-hour battery (or a battery with approximately 83 minutes of reserve capacity) can be expected to deliver at least 2.5 amps for 20 continuous hours, or at least 1 amp for 50 continuous hours. Note, however, that at current drains much higher than those specified at the 20 hour rate the capacity of the battery starts to decline due to internal losses and chemical inefficiencies at high currents. Consequently, this same battery might only be able to deliver 5 amps for nine hours (45 effective amp-hours), instead of the 10 hours (50 theoretical amp-hours) implied by the battery's amp-hour rating. Bigger batteries can deliver higher currents without incurring this effect.

Like all lead-acid batteries, the life expectancy of a deep-cycle battery is directly dependent upon how heavily the battery is discharged before being recharged. Batteries that are routinely discharged to only 20 percent of their rated capacity have a much shorter life expectancy than identical batteries that are rarely discharged below 50 percent. This same trend applies at the extremes—few batteries that are completely discharged will last for more than a few such cycles, and most batteries that are never discharged below 80 to 90 percent of their capacity will last almost indefinitely (given proper maintenance). The moral: Don't buy a 100 amp-hour battery if you are planning on routinely using all 100 amp-hours between recharges. A good rule of thumb states that a deep-cycle battery should be recharged before 80 percent of the capacity has been drained, with 50 percent being even better. Fifty percent discharge represents a good compromise between battery life expectancy and reasonable battery bank size. Therefore, you would do well to buy at least 200 amp-hours worth of batteries to meet your anticipated 100 amp-hour discharge "budget."

Ambient temperature also has a strong effect on battery performance. Most batteries are rated at around 80 degrees Fahrenheit. At higher temperatures they are capable of greater capacity, but their life span is shortened, due to the acceleration of detrimental chemical reactions. At lower temperatures, they last longer than normal (provided the electrolyte is not allowed to freeze), but their capacity drops. At 32 degrees F, typical capacity is reduced by 35 percent; at 0 degrees F, it is reduced by 60 percent; and at minus 20 degrees F,

	Charge Cutoff Voltage:	Maintenance Voltage:	Equalization Voltage:
Wet-Cell Battery @ 80° F.	14.4	13.5	16.3
Wet-Cell Battery @ 100° F.	13.9	13.3	15.8
Gel-Cell Battery @ 80° F.	14.4	13.8	(na)
Gel-Cell Battery @ 100° F.	14.1	13.8	(na)

Table 2. Non-sealed wet cell battery states.

Approx. State of Charge:	Specific Gravity:	No-Load Voltage:
100%	1.270	12.70
75%	1.250	12.50
50%	1.190	12.30
25%	1.150	12.10
DEAD!	1.120	11.80

Table 3. Suggested charge and equalization voltages for various batteries.

it is reduced by better than 80 percent. Their ability to accept a charge also drops along with the thermometer. In general, the best tradeoff between efficiency and long life occurs when the battery is maintained at around room temperature.

As a battery is discharged, the sulfuric acid solution inside each cell is gradually converted to ordinary water. Consequently, the specific gravity of this solution also drops as the battery discharges; this change can be easily measured with a hydrometer in order to determine the battery's state of charge. A good battery hydrometer includes a temperature correction scale (specific gravity versus battery charge varies somewhat with temperature), and will often provide readings that are more precise than those obtained with a voltmeter. Specific gravity readings should be taken by inserting the hydrometer suction pipe into the battery cell, squirting the electrolyte into and out of the hydrometer several times (electrolyte agitation improves accuracy), and then reading the hydrometer while the suction tube is still inserted into the cell. Keeping the suction tube in the cell while taking readings minimizes the chance of spilling the electrolyte on feet, kneecaps, or any other exposed appendages. Read the hydrometer scale at the center of the fluid inside the tube, not at the edges. Note that any heavy battery charge or discharge currents drawn just prior to taking specific gravity or voltage measurements will have an adverse effect on the accuracy of the readings. Specific gravity readings are also helpful in determining the overall health of a battery. For example, differences in specific gravity of more than 0.050 between any two individual cells in a battery generally indicate that the battery is headed for problems. By taking specific gravity readings every month or so you can catch battery problems before they cripple the entire system.

Table 2 is helpful in determining the state of charge of a battery, using either a voltmeter or hydrometer. Note that this table is applicable only to the non-sealed wet-electrolyte batteries. For obvious reasons, a hydrometer should never be used on a sealed battery (wet or gell).

What To Buy

Among the deep-cycle variants, the most common type is the RV/Marine, typically sold by hardware and department stores in automotive package (or "group") sizes 24 and 27. Typical ratings for this class of battery are 70 amp-hours (110 minutes) for the size 24, and 105 amp-hours (170 minutes) for the size 27. These batteries represent a reasonable value in smaller solar systems, or in installations where space is at a premium. However, as deep-cycle designs go, they are lightweights, with relatively short

life expectancy in heavy service. This deficiency is primarily due to the use of thin lead plates used in their construction, and the low antimony content of the plates themselves. The next most common deep-cycle version is probably the golf cart/electric vehicle, typically sold through battery supply houses, some wholesale clubs, and an occasional department store (frequently by catalog only). These batteries are all of 6 volt design (you use two in series to get 12 volt banks), and typically cost a tad more per pair than a single size 27 RV/Marine battery. They provide superior service in most solar applications (due to thicker plates and higher antimony content), and probably represent the best value for small to mid-sized installations. Typical ratings are 220 amp-hours, or 400 minutes of reserve capacity.

Industrial (floor scrubber) batteries are probably best described as golf cart batteries on steroids. They are 6 volt, with much taller cases than golf cart batteries. They are typically rated at around 350 amp-hours, and they also make excellent choices for small-to-mid-sized solar applications. They are available from the larger battery supply houses, or may be special-ordered (along with ordinary golf cart batteries) from auto parts stores like NAPA. High-quality deep-cycle batteries for marine applications are manufactured by Surrrette and by Rolls, in a variety of sizes. They are of very heavy construction, with very thick, high antimony content plates. Many marine supply houses stock them, and they work very well in solar applications.

For non-mobile installations, really large deep-cycle batteries are often employed. For example, 12 volt electric fork lift batteries are available with typical ratings of 1,000 amp-hours. Life expectancy is around 10 years, and the cost brand-new is under \$2,000. Surplus telephone cells are also popular, with ratings of 1,200 to 2,500 amp-hours being commonplace. These cells are sold individually (each cell is 2 volts and weighs between 300 and 500 pounds). Life expectancy is greater than 20 years for new ones.

A good used set will have at least 10 years of life left in it, and is available for around \$400 to \$800 per 12 volt group. Gell-electrolyte (gell-cell) batteries are becoming cheaper and more popular for solar applications. Available in group 24, 27, 4D, 8D and 6 volt golf cart sizes, they offer very good performance, with virtually zero maintenance. Where ordinary "wet cell" batteries require monthly checks of electrolyte levels, the gel cells are completely sealed, with nothing to replenish. They also offer higher charging efficiency than ordinary batteries, and provide slightly higher output voltage down to complete discharge. Examples of this class of battery are the

Johnson Dynasty, Exide Nautilus Megacycle, and Dryfit Prevalier/Sonnenschein/Deka brands. Don't confuse these batteries with the "maintenance-free" wet-electrolyte RV/Marine batteries being sold in some department stores under brand names such as Delco Voyager and GNB Stowaway. Unlike the true gel-cells, these batteries offer little improvement in performance over the standard RV/Marine models.

How To Keep Them Happy

Although routinely overlooked in the battery manufacturers' literature and in many references, most deep-cycle batteries (with the exception of the gell cell and other totally-sealed varieties) are benefited by a periodic, controlled overcharge, often referred to as an equalization charge. To equalize a battery, the charging is allowed to continue for some time past the point at which the battery is normally considered to be "full," taking care to avoid excessive battery heating or electrolyte boil-off. In a typical equalization cycle, the battery voltage is allowed to rise to approximately 16 volts, where it is maintained for up to eight hours by adjustment of the charging current. This process helps to mix up the electrolyte, which otherwise tends to "stratify" (e.g., separate into overlapping layers of acid and water). It is also useful in removing some sulfate deposits. When performed properly, equalization doesn't make the battery boil over, but does produce fairly vigorous bubbling. At the termination of this cycle you can expect to add some water. Most battery manufacturers consider one equalization charge a month to be appropriate for batteries that are in a continuous state of charge and discharge; less often is adequate for batteries that see a lot of standby service. Due to the generation of considerable gas that accompanies this process, equalization should *never* be performed on a sealed or gell-electrolyte battery. (Because their electrolyte is gelled, stratification is generally not a problem with gell-cells, anyway). Also, most 12 volt appliances will not tolerate 16-plus volts, so remember to disconnect everything before you equalize. Table 3 summarizes the suggested charge and equalization voltages for various batteries.

Finally, remember that lead-acid batteries generate highly explosive gasses. The larger the battery bank, the more gas produced. Don't mount any battery in an unvented location, and avoid any sparks or open flame around the battery (particularly during and shortly after recharging). Making or breaking electrical connections at the battery terminals is particularly dangerous. Battery explosions often shower large areas with acid. Wear eye, face and skin protection, and give the bank plenty of time to "air out" before attempting any maintenance or inspection.

If you are buying new solar panels, you will probably find that models in the 47 to 65 watt range represent the best value (e.g., most watts per dollar). If that size range will serve your needs without overkill. This range is where the sales volume currently lies for large-scale power production (e.g., for homes and small businesses). Excellent quality is the rule throughout the industry, with limited warranties typically ranging from 10 to 12 years. Actual expected life is anyone's guess, but figures of 20 to 30 years are routinely tossed around. There isn't too much standardization in panel sizes among the offerings from different manufacturers, so pick your brand and mounting hardware carefully. Also, the power density (amount of power produced per square inch of panel area) varies subtly from one model and manufacturer to the next. This means that in some applications where space is very limited, Model X might meet performance objectives where Model Y wouldn't. In picking a panel model, you should consider the anticipated temperature operating range of the panels, the efficiency of your charge controller, and your battery maintenance requirements. As the temperature of a solar panel rises, its output voltage drops. If your panels will be located in a very hot climate and/or are mounted in such a manner as to hinder air circulation around both surfaces, you should limit your panel selection to models that offer the highest charging voltages (typically around 17 volts at rated output current). Some of the lower-voltage "self-regulating" panels are designed to be used without a charge controller in applications where the load attached to the battery is anticipated to be constant enough to avoid boiling dry the electrolyte. Since the output voltage of these panels has been intentionally reduced, the likelihood of battery damage is small. Unfortunately, so is the likelihood of ever fully recharging the battery. High temperature becomes even more important if you will be periodically equalizing your batteries, since this process can require better than 16 volts under full load from the panels.

Finally, if the output voltage of your panels is marginal under hot conditions, a charge controller with excessive internal losses may aggravate the problem. Try to pick a controller that has less than 0.5 volts of drop under your maximum anticipated charge current (the controller described in the accompanying article has virtually no internal losses). If you will be buying your panels surplus, you are pretty much stuck with what's available. If possible, obtain permission to return the panels for a refund if an initial test shows that they are producing considerably less than their new rated current and voltage. Look for water leaks in the seams of the panel glass. If the panel has

Note (Calculating R1): Due to the large amount of current and very low resistance value of R1, this resistor is best built from scratch. R1 is an ammeter current shunt, and physically consists of nothing more than a precise length of 14 gauge household wire. The proper wire length is shown in Table 1. There is nothing unusual about building it—it can be wrapped in a coil, wadded-up, or just left hanging. As shown in the schematic, meter M1 is connected through it with a couple of ordinary hook-up wires. Since the vast majority of current is carried through R1, the wires to the meter can be of most any convenient gauge.

The value for R1 can be determined after the decision is made on maximum current through shunt load R2 and the full scale meter movement current and meter resistance. All current meters have some small value of resistance. If you don't know that value, you can calculate it with a simple experiment:

Let I_M = full scale meter movement current

R_1 = meter shunt resistance

I_L = maximum load current into the shunt R_2

R_M = resistance of the current meter

Take a variable resistor that has a value of $2 \times 12 \text{ volts}/I_M$.

If the I_M current is 1 mA, then the variable resistor should be greater than 12 kΩ or approximately 30 kΩ. Connect the meter and variable resistor (*adjusted to maximum resistance*) as shown in Figure 6. Slowly adjust the resistor until the meter is reading full scale (1 mA in this example). Now measure the very small voltage drop across the meter with a DVM. This voltage drop divided by the full-scale current meter reading will be the meter resistance R_M .

Now the value of R1, the shunt resistor, can be determined for the full scale current meter with the calculated meter resistance of R_M :

$$R1 = \frac{I_M}{I_L} R_M$$

The Solar Control-ar

Continued from page 36

bare wires for electrical connections, wiggle the wires while checking the output under load to insure that the panel connections are not intermittent. A panel with faulty connections will often show sufficient output voltage under no load, but will drop to almost no output when any appreciable current is drawn. Beware of stolen panels. Some bargain panels being sold at flea markets were originally "liberated" from mountaintop radio sites or RV'ers in the desert. If the panels are engraved or otherwise marked, make sure that the seller has a believable story as to their ancestry. Take names and addresses.

In most installations, you have a choice between tracking the sun with the panels, or leaving the panels in a fixed position for the day. Auto-tracking panel mounts are commercially available (or can be fun to design

and build yourself), but they do add some expense and maintenance requirements to the system. If the size of your system is marginal, buying additional fixed panels might be just as cost-effective as installing trackers. During the wintertime, much of the advantage in tracking the sun is lost, since it never rises very far above the horizon, and doesn't travel very far horizontally between sunrise and sunset. Also, on overcast days, it makes little difference which direction the panels are facing, but installing additional panels will always provide some additional output. However, if you don't use a tracking system, be sure to include provision for seasonally changing the elevation of the panels. An adjustable bracket costs little more than a fixed mount, and the improvement in power output is almost always significant. **73**

SCARED OF THE CODE?

IT'S A SNAP WITH THE ELEGANTLY SIMPLE MORSE TUTOR ADVANCED EDITION FOR BEGINNERS TO EXPERTS—AND BEYOND

Morse Code teaching software from GGTE is the most popular in the world—and for good reason. You'll learn quickest with the most modern teaching methods—including Farnsworth or standard code, on-screen flashcards, random characters, words and billions of conversations guaranteed to contain every required character every time—in 12 easy lessons.

Sneak through bothersome plateaus in one tenth of a word per minute steps. Or, create your own drills and play them, print them and save them to disk. Import, analyze and convert text to code for additional drills.

Get the software the ARRL sells and uses to create their practice and test tapes. Morse Tutor Advanced Edition is approved for VE exams at all levels. Morse Tutor is great—Morse Tutor Advanced Edition is even better—and it's in user selectable color. Order yours today.

For all MS-DOS computers (including laptops). Available at dealers, thru GST or 73 or send \$29.95 + \$3 S&H (CA residents add 7.75% tax) to:

CIRCLE 193 ON READER SERVICE CARD

ARE YOU BUILDING A Packet Network?

Join the latest Packet Radio excitement - building the networks that make it all possible. Using ordinary Packet TNCs with network software installed, you too can expand the existing network, or start your own! ANS has all of the hard-to-find parts that will bring it all together:

The 6-port NETRIX Diode Matrix Board connects TNCs together to form a network switching node, where packets are routed towards their final destination. It uses DTE-9F connectors, is designed to eliminate expensive, unsightly cables, and works with either TNC-1 or ROSE networking software. \$24.95 as a complete kit, or \$39.95 assembled. Adapters for DRSL, MFI or AEA TNCs are only \$2.49 each - specify TNC model.

The WireModem Adapter allows one TNC to connect (via a WireLan Matrix) to up to 5 other TNCs. Connect switching nodes together to make a SuperHub, an inter-network gateway, or to attach a few servers (like a BBS or DX Cluster) directly to the network via wire (or superior performance! Only \$2.95 as a kit, or \$4.95 assembled. WireLan Matrix \$1, assembled.

To bring it all together, ANS offers TNC to Radio cables (\$9.95) and a Power Supply & TNC cable for the popular TEKK KS-900 link radio (\$24.95).

Please write for more information. To order, send check or MO, add \$3 S/H, NJ address add 6% tax. All orders shipped 2-Day air! Your Satisfaction is Fully Guaranteed.

Ramsey Electronics FX-146 Transceiver Kit

Ramsey Electronics

793 Canning Parkway

Victor NY 14565

Telephone: (716) 924-4560

Price Class: \$149.95 without chassis/knob kit;

\$24.95 for matching CX chassis/knob kit.

Roll your own 2 meter rig.

Okay, you're a typical ham and like to fire up the ol' soldering iron once in awhile. Let's say you just found \$175 stashed away for a rainy day or the next trip to the Dayton Hamvention. (Sometimes they are one and the same!) What would you buy? Let's see, how about a 4 watt, diode-programmable, packet-ready 2 meter synthesized transceiver kit? And it has to have a snazzy-looking cabinet kit with knobs. Wait, it should also be able to work with virtually any speaker/mike on the market! And the receiver coverage should be broadband to pick up NOA weather signals.

Kinda picky, aren't you? Good thing that John Ramsey of Ramsey Electronics thinks the same way you do, and makes the FX-146 transceiver kit!

Overview

Yes, the FX146 is a pretty neat piece of work, and a proud successor to the original FTR-146 kit, introduced in 1991. For your money, you get a state-of-the-art radio with a professionally-screened G10 circuit board that's easy to put together, easy to test, and works very well on the air. Bells and whistles have been kept to a minimum, with the emphasis on a well-thought-out design employing the Motorola 145152 phase-lock-loop synthesizer chip and your everyday, garden variety 1N914 diode for frequency selection (see Photo C).

The concept behind this radio is simple, but clever: Build your own 2 meter radio, and while you do you'll learn how all of the parts and circuitry work. Should repairs be required, you won't hesitate to open the cover and "dive in" to fix it. What's more, you'll take more pride in this radio precisely because *you built it your-*

self. (And, of course, let's not forget that you saved a few dollars along the way!)

I bought my FX-146 at Dayton '93 strictly on impulse—it was, after all, a rainy day—so after a brief discussion with Tom Hodge WA2YTM at the Ramsey booth, my wallet was lighter and my carry-all bag somewhat heavier. Tom figured it would take me about three evenings to put the kit together and get it on the air. (Note to novice builders: The term "evening" is a standard measurement among kit builders that has about as much relevance today as "fur-longs per fortnight." A more realistic appraisal of the time required to build this kit might be six to eight hours, depending on how methodically you work.)

When you first open up the kit package, you'll notice all of the parts and the circuit board neatly sorted into clear ziplock bags. All parts are clearly identified, and all ICs are wrapped in foil for static protection.

If you bought the chassis and knob kit, it too is packaged carefully to minimize scratching. But the best part of the kit is the instruction manual, which answers every possible question you could have as you proceed with assembly.

This manual is over 130 pages long and contains detailed parts lists, assembly instructions, schematics, a parts overlay, and a good deal of what I call "pep talk"—additional material not usually found in kit instructions which is designed to motivate you to want to build the kit and have fun while doing so. In some cases this is nothing more than illustrating how simple the step-by-step procedure is.

The manual also provides a good many helpful notes and tables on how synthesizers

work, how to select the right antenna, and how to select and program your desired channels. I've built quite a few kits over the past 25 years, so believe me when I tell you the manual can make or break a kit! The standard for me has always been the Heathkit manuals, and the FX-146 manual compares favorably with any I've seen from Benton Harbor.

Construction

Kit assembly is fairly simple. I suggest locating a number of half-pint plastic deli containers to hold all parts as you proceed. Another useful trick is to double up a piece of masking tape, stick it to your work surface and use it to hold loose components until needed. Many of the parts supplied are already attached to taped rolls, such as the 1N914 diodes and many small capacitors and resistors. A low-wattage iron (say, 40 watts) as well as a pair of diagonal cutters and small pliers will suffice as your tool kit for most of the assembly.

Like the aforementioned Heathkit manuals, Ramsey employs the double-check system during assembly. You locate the part, install it, solder and then "check off" the corresponding box next to that instruction. After you finish a section of the board, you go back, inspect your work and check off again to confirm you did the step correctly. A simple idea, but it really works! Even experienced kit builders such as myself find this system very helpful.

Before you begin each section, there is a thorough description of the circuit and how it works—sort of a mini-tutorial on the fly. After reading these sections, you then proceed to actual assembly. Ramsey's approach is to divide the construction into 11 stages. As you finish each stage, you can perform a short test to make sure everything was done correctly. This will do wonders for your confidence as you proceed to the next section, and should a problem develop it can be isolated and fixed quickly.

Once all of the stages have been tested (with the exception of the RF amplifier), you'll need to load up at least one diode matrix into a channel. I found the easiest way to do this was to raise up the edges of the PC board on two wooden blocks about three inches above my workbench. This allows you to drop all of the diodes through their PC mounting holes and solder the cathode ends to the U-shaped buss bar. Once you've done this, flip the board over and solder the anode ends to the PC board traces.

Photo A. The Ramsey FX-146 2m FM transceiver kit.

Photo B. Close-up of the FX-146 (top view) showing all components. Note the clean, simple design.

Clip excess leads off carefully.

One word of advice when doing this: Make sure you solder the cathode-to-buss connections carefully. It might even be advisable to bend the diode leads into a hook and hang them over the buss wire before soldering. I had

a few cold connections and certain channels wouldn't work when selected.

Performance

The FX-146 works surprisingly well, given the simple design. Front-end sensitivity is

claimed to be less than $0.35 \mu\text{V}$ for 12 dB SINAD, and my tests showed this figure to be closer to $0.30 \mu\text{V}$. Adjacent channel rejection is specified to be down 6 dB ± 7 kHz, and -60 dB ± 15 kHz, which is pretty tight. An option included with the kit will improve front-end performance even more for those in high-RF-density urban areas, although I haven't found it necessary yet.

The squelch threshold is specified at 0.25 μV , and again I found this to be somewhat lower. Squelch hysteresis performance is good, but I found the loud "pop" objectionable each time the squelch was broken or reset. This is caused by the "gating" of the audio output IC, a LM380 linear device. A call to the factory resulted in a modification to change C48 from a 0.001 disc to a $10 \mu\text{F}$ electrolytic, ostensibly to filter out this pop when the IC turned on. The fix made a slight improvement, but the pop is still somewhat annoying.

The FX-146 is set up to select any of 12 preprogrammed channels, the theory being that most users of synthesized radios rarely use more than 10 to 12 memory channels to begin with. This is certainly true in my case, as I use a Kenwood TM221A with 10 memories for day-to-day 2 meter operation. Actual channel selection uses a conventional 12-position single-pole switch to send 5 volts to the desired channel buss. It's not sexy, but sure is simple and reliable! Synthesizer lock-up

66 The R8 is like a breath of fresh air, with its ground-up engineering and up-to-date digital control from the front panel... a quality HF receiver of American manufacture that should successfully compete on the world market. 99

Bill Clarke
73 Amateur Radio Today

66 Overall, the Drake R8 is simply the best radio we have ever tested for quality listening to programs... There's nothing else quite like it. 99

Lawrence Magne
Monitoring Times

66 The best of the best for high-quality listening to news, music and entertainment from afar. Superb for reception of faint, tough signals. 99

Tabletop Receivers for 1992

WHAT IN THE WORLD ARE YOU LISTENING TO?

The world is an ever-changing place, but there is one thing you can rely on to remain the same...the Drake reputation for American-crafted, quality communications products and unsurpassed customer service. Now, the Drake R8 Worldband Communications Receiver has been heralded by the experts as "the best of the best," delivering "unparalleled all-around listening performance" that is "right up there with the best for DXing."

So if you want to keep up with a changing world, and you're not listening to a Drake R8, we'd like to suggest you make a change. Call 1-800-723-4639 today for more information about the R8, to find the dealer nearest you, or to order an R8 direct from the factory with a free 15-day trial period. If you're not impressed by Drake's quality, performance and ease of operation, all in a receiver costing less than \$1,000.00, return the R8 Receiver within 15 days, and we'll refund your money in full, less our original shipping charge.

The world is a big place. If you want to hear it all, listen to a Drake R8. If you're missing it, what in the world are you listening to?

Photo C. Close-up of the diode matrix area, showing the buss connection technique.

Photo D. Close-up of the final amplifier assembly, showing the trimmers and output coils.

was quick and reliable on every channel (except where I made a couple of cold solder joints).

On-air reports were good. Initially, I was told my audio had a fairly noticeable hum which disappeared when I replaced the ICOM HM-9 speaker/mike with an HM-54. Transmitted audio quality was excellent, and there's plenty of headroom on the microphone gain control although there is no separate deviation control. The FX-146 uses true direct frequency modulation, by the way.

Output power is specified in the 4 to 6 watt range, but try as I might, I couldn't squeeze more than 3.5 watts out of the FX146 anywhere in the band. (I used a Bird 43 with 10C and 5C slugs plus a Bendix 50 ohm termination to make these measurements.) Note that the driver and final RF stages use lumped, Hi-Q tuning coils and trimmers (Photo D), and once you've peaked up the trimmers you'll see a fall-off in power if you move up or down the band more than half a megahertz. Still, this power level is more than adequate for most

contacts through a repeater, and with an omnidirectional antenna or small beam, you'll get out a good distance.

Overall, the FX-146 represents an excellent value for the money. Its performance is on a par with any other 2 meter transceivers on the market today (other than the squelch pop), and it is easy to assemble and test . . . thereby making it easy to troubleshoot later if repairs are needed. If you really want to "build it yourself," you'd be hard pressed to beat this kit for fun and utility.

Serving The LORD
Since 1987

\$49.95!

THE POWER STATION

The POWER STATION is a 12V x 6.5 AmpHr gel-cell battery complete with voltmeter, wall charger and a cord for charging via automobiles. It will power most

HT's at 5 Watts for 2-4 weeks (depending upon how long-winded you are). Also VHF, UHF, QRP, or HF mobiles such as the KENWOOD TS-50 (at 50W). There are no hidden costs, all you need is your mobile, HT power cord or cigarette lighter adapter.

The POWER STATION provides 12V from a cigarette plug and has two recessed terminals for hardwiring. A mini-phone jack with regulated 3V, 6V, or 9V output can be used separately for CD players, Walkmans, etc. THE POWER STATION can be charged in an automobile in only 3 hours, or in the home in 8 hours. The charger will automatically shut off when the battery is completely charged, so you can charge it even when it has only been slightly discharged, (unlike Ni-Cads that have memory). Our charging circuit uses voltage sensing circuitry, other brands are timed chargers which always charge the battery a full cycle, this damages their battery and shortens its' life if it only needs a partial charge. The POWER STATION has a voltmeter that shows the exact state of charge of the battery, not worthless idiot lights that tell you "YOUR BATTERY IS NOW DEAD." The voltmeter can even be used to measure voltages of other sources.

To order, send check or money order for \$49.95 + \$8.50 for shipping, along with your shipping address and telephone number to:

Azden AZ-61 6m FM Transceiver

Advanced features in the palm of your hand.

Azden Corporation
147 New Hyde Park Rd.
Franklin Square NY 11010
Telephone: (516) 328-7500
Price Class: \$379 plus \$5 shipping

The 6 meter band is brimful of excitement for every ham, from the new no-code Technician to the seasoned Extra Class. But don't get the wrong idea—even though 6 meters is exciting, there's still plenty of elbow room in the sparsely-occupied spectrum from 50 to 54 MHz.

FM is the predominant mode on 6 meters. There should be no FM operation below 50.30 because this area is reserved for the SSB and CW weak-signal operation found in large multimode mobile and gas station equipment. Remember: *No FM below 50.30 MHz!*

A good way to get started in 6 meter FM communications might be to pick up a good hand-held transceiver. And while you may think that a measly 3 or 4 watts output won't do much on the 6 meter band, keep in mind that this is the same amount of power output found in 2 meter handhelds.

One unique characteristic of the 6 meter band is it allows small hand-held transceivers to work distant repeaters just as far as on 2 meters, and will sometimes give you *real* FM excitement during periods of ionospheric sporadic E band openings. You may find yourself working through a repeater 1,200 miles away, thanks to brief skywave band openings. And keep in mind that sporadic E band openings are not dependent on the 11-year solar cycle. You can count on 6 meter skywave activity during the summer and fall seasons. And while it may only last for a few minutes to a few hours, hand-held operation gets exciting—especially if you are hooked into an outdoor antenna.

The Azden AZ-61 6 meter hand-held transceiver is available direct from the manufacturer: Azden Corporation, 147 New Hyde Park Road, Franklin Square NY 11010

(516/328-7500), Attn: Sid Wolin K2LJH, Manager. The Azden line of amateur radio equipment has been around as long as the synthesized 2 meter transceiver, and is now available direct from New York.

the Azden 2 meter owner's manual. We are told that a 6 meter manual is in the works, but the variations between how a 2 meter Azden works and how the little 6 meter handheld works are minor. Well, almost . . .

"A good way to get started in 6 meter FM communications might be to pick up a good hand-held transceiver."

This Azden looked perfect for the Southern California 6 meter Club. They were searching for a quality hand-held 6 meter transceiver that they could order in quantity. The unit

channels in the VFO and memory mode are slightly different for the 6 meter unit than what is described in the 2 meter owner's manual.

The Azden 6 meter handheld is packed with all the usual accessories, including the 8"-long flexible rubber antenna, sturdy belt clip, and the large 12 volt, 600 milliamp hour, rechargeable battery. The battery is shipped uncharged from the manufacturer, so you will need to drop it in its included pull-out desk charge stand and let it cook for at least six hours before turning on the juice. The charger puts out 300 milliamps, and the transformer is housed in the plug-in assembly, hogging an adjacent 110 VAC receptacle beside it if you plug it into a power strip. And be assured that this charging base setup is unique to Azden's line of handhelds, and there is zero chance that it is interchangeable with any other handheld from any other manufacturer. Why won't manufacturers ever standardize their batteries or chargers?

On the top of the handheld is a 12-volt DC input receptacle, with the center-pin positive. *Watch out—even though you may already have a mobile 12 volt hand-held plug that looks similar to this jack, make absolutely sure that your 12 volt plug has the center hole as positive.* Some other handhelds run positive on the outside of the plug, not the inside hole.

The Azden AZ-61.

sounds fine on the air, and most members are relatively satisfied with their purchase.

Features

The review transceiver was shipped with

Reverse polarity means instant destruction to the 12 volt DC input circuitry to this handheld.

During our testing, we discovered that the 12 volt input circuit does not charge the attached battery. This was not a surprise—some handheld manufacturers provide a 12 volt regulator for mobile charging, but others don't. We *did* find that there is a small "buffer" circuit off the external 12 volt line to help minimize alternator noise that sometimes creeps through on transmit. On this unit, we judged this circuit as average. If you have an aggressive 12 volt alternator, you're going to hear it over-transmit on the Azden—as you would on any inexpensive handheld.

Operating: Read the Book First

The Azden 6 meter handheld is not easily operated without a thorough review of the instruction book. Most seasoned hams can figure out the simple operation and memory channel steps of most handhelds without a book—except for maybe the Kenwood 78—but with this Azden, you must read first.

To enter a frequency like 52.525 MHz, first hit the "VFO" key, then enter "2," "★" (Del), "5," "2," "5," and the unit continues to blink for about a second until it locks on. If you don't hit the "★" (Del) key to set the decimal point, the unit won't take the frequency, and will continue to flash at you for about 10 seconds after your last futile keystroke. After 10 seconds, it figures that you need some help, and goes back to the last valid frequency entered. Remember: *Read the book before operating.*

Once the set accepts the valid frequency entry, it reads out "52.525" and does a nice job of capturing any signal out there on frequency. The receiver was plenty sensitive down to 0.08 μ V, and with dual conversion was tight enough to offer excellent selectivity from other stations slightly higher and slightly lower in frequency. The Azden 6 meter handheld utilizes a hard-squelch circuit, and marginal signals will cause the squelch to clamp with a noticeable "pop" as an internal transistor clamps the audio off. But if you accidentally forget and turn down the volume, this hard squelch "pop" might get your attention in a quiet room—there may be someone on channel trying to get through. Few handhelds offer "soft squelch," and in strong signal areas where most operating is through repeaters, the hard squelch in this unit is perfectly acceptable.

Audio output and fidelity from the internal speaker are excellent. If you plug in the optional external speaker/mike, you'll have more than enough audio to hear any call to you (if the speaker/mike is anywhere near your ear). Good news: Many of the generic speaker/microphones have the same exact plug complement that the Azden accepts. Some of the external crossband speaker/microphones run a little hot on transmit modula-

tion, so double-check your levels after you get your external setup plugged in.

The Azden 6 meter handheld offers 40 channels of memory, 20 in memory bank A and 20 in memory bank B. You select the memory bank channel by pressing "function" A/B, and then pressing the number of the memory channel desired. To enter a frequency into a memory channel, you must first recall the memory channel you want to program. Then press VFO, and set the frequency.

For the offset, you hold the function button on the side of the unit while depressing the

CTCSS decode
CTCSS encode
Frequency step
Scan hold time
A-bank scan skip
B-bank scan skip
Automatic power off time
Battery saving time
DTMF pager/calling

And there are even a few more things that you can do with this handheld, which we would classify as "advanced operating features."

"The set is too darn complicated," comments an active 6 meter enthusiast. I didn't

find this necessarily true—I must admit it's certainly not a handheld that you can take out of the box, and start punching in frequencies, offset, and tone without looking at the instruction manual (like some handhelds I know of). But if

you do read the instruction manual, the operating and programming is easy.

This IS an advanced-feature handheld, so it takes about an hour of programming in order to get the "feel" for how frequencies, offset and tone get memorized.

About the only thing I found a problem with was slow synthesizer lock time which all but eliminates the capability of cycling through frequencies with the up or down arrow looking for activity. As soon as you press the up and down arrow frequency slew button, the receiver blanks out until you release the button. You could electronically scan the 6 meter band for activity, but I like to go into the manual mode, and search down at the cordless telephone frequencies near 46 MHz and 49 MHz and see what all I can pick up. (Cordless is legal.) Lots of excitement here!

So, I like it. I like the Azden AZ-61 6 meter handheld a lot. Just be sure to read the instruction manual first!

73

"Good news: Many of the generic speaker/microphones have the same exact plug complement that the Azden accepts."

number 9 key. This allows you to select no offset simplex, minus 500 kHz offset down, or plus 500 kHz offset up. No oddball offsets are available on this unit.

To encode a subaudible tone, you hold the function button again and push the zero key. This activates the "PROG" program display, and you cycle with the pound key (#) past "T.SQ" tone squelch decode, and TO "Tone" for tone encode. Cycle up to the desired tone by exact tone frequency, and then wait approximately five seconds for the unit to time out of the program mode, and get you back into the VFO display mode. Now depress the function button again and the "3" key, and this brings up the word "Tone," indicating CTCSS encode each time you transmit.

Now, memorize this package into any one of 20 + 20 memory channels by holding the "ENT/MW" pound key until you hear a beep.

There are several other options that you could program on each memory channel, too:

ARRL 6 Meter Wavelength Band Plan, 50.0-54.0 MHz

MHz	Use
50.100-50.300	SSB,CW
50.100-50.125	DX window

Amateur Radio Via Satellites

Andy MacAllister WASZIB
14714 Knights Way Drive
Houston TX 77083

New Satellites

The flight of Ariane V-59 was originally scheduled for September 1st. The primary payload, SPOT-3, encountered technical difficulties requiring a launch slip to late September. If all goes as planned, six smaller satellites will be mounted on a ring at the base of SPOT-3. They include Stella, Healthsat, PoSat-1, Itamsat-A, Kitsat-B and Eyesat-A. Two of the satellites are purely commercial, two contain both commercial and amateur payloads, and two are dedicated to amateur radio service.

The ejection sequence has SPOT-3 separating first, followed by Stella, Kitsat-B, PoSat-1, Healthsat, Eyesat-A and Itamsat-A. The OSCAR (Orbiting Satellite Carrying Amateur Radio) numbers associated with the new satellites are currently under discussion since Arsene has not yet been given the name Arsene-OSCAR-24. If Arsene is given a number, the suggested OSCAR numbers for the new hamsats are: Kitsat-OSCAR-25, PoSat-OSCAR-26, AMRAD-OSCAR-27 and Itamsat-OSCAR-28. The expected orbit of the new satellites is 300 km high with an inclination of 38.7 degrees. This is identical to that of the microsats, OSCARs 14-19.

Stella and Healthsat are the commercial secondary payloads. Stella is a German geodetic satellite and Healthsat is a test platform for small ground-station activity in support of efforts by VITA (Volunteers in Technical Assistance) and Sattelite. It is a digital system that operates at 9.6 and 38.4 kbps (kilobytes per second).

The combination amateur/commercial satellites include PoSat-1 and Eyesat-A. PoSat comes from the

Portuguese organization LNETI. The satellite's purpose is to provide experience to Portuguese nationals for the construction and operation of satellites.

PoSat-1 was built at the University of Surrey in England by members of the UoSat team and a group of four engineers from Portugal. The satellite carries an earth-imaging camera capable of 200 meter resolution, a CCD (charge-coupled device) camera as a star sensor, a cosmic-ray detection experiment, a Trimble GPS (Global Positioning System) receiver and a DSP (Digital Signal Processing) experiment with two Texas Instruments processors. PoSat-1 will support 9.6 and 38.4 kbps operation on the amateur band frequencies. The primary amateur activity will likely involve the imaging experiment. Note Table 1 for details.

Eyesat-A is the first commercial satellite built on a microsat bus structure. It was manufactured by Interferometrics, Inc. of Vienna, Virginia. The amateur radio portion of this satellite was produced in cooperation with AMRAD, an experimentally-oriented organization in the Virginia suburbs of Washington, D.C. The satellite is capable of digital communication speeds from 300 to 19.2 kbps on the amateur bands. Although Table 1 shows operation only up to 9.6 kbps, onboard experiments can be initiated for operation above this. A crossband voice repeater with 70cm uplink and 2 meter downlink is also a possibility.

Kitsat-B and Itamsat-A are the two satellites dedicated to amateur-radio service to be carried aloft on the Ariane V-59 mission. Both satellites promise to be extremely popular additions to the current fleet of digital hamsats.

Kitsat-B is the second satellite from KAIST (Korean Advanced Insti-

Photo A. Dick Jansson WD4FAB attended the AMSAT-UK meeting to present data on the new structure for the Phase-3-D satellite. (WSIU photo.)

Photo B. Viktor Kudielka OE1VKW discovered the orbital mechanics responsible for the eventual decay of AMSAT-OSCAR-13's orbit. (WSIU photo.)

tute of Science and Technology). While the first one, now known as Kitsat-OSCAR-23, was built at the University of Surrey and is based on the Surrey satellite frame, Kitsat-B is a completely Korean effort. This represents an important phase in the technology transfer between Surrey and KAIST. The new Kitsat carries many of the same type payloads as K-O-23, but has advancements in imaging capability and data transfer speed. More information on the scientific components of Kitsat-B can be found in the June "Hamsats" column. Operating frequencies are shown in Table 1.

Itamsat-A was built by AMSAT Italy and incorporates modifications and advances to the original microsat design. These upgrades have been used to modify designs for additional hamsats under construction in other parts of the world. While data communications rely primarily on the PSK (phase-shift keyed) modulation techniques of the current microsats, a 9.6 kbps system using FM up and down has been incorporated for compatibility with the highly successful UoSat and Kitsat designs now in orbit.

Future Satellites

In addition to those hamsats scheduled for the V-59 launch, UN-AMSAT from Mexico and RS-15 from Russia are ready and waiting for their flight to space. CESAR-1 from Chile, SUNSAT from South Africa, HUTSAT from Finland, Sedsat from the U.S., Guerwin-1/Techsat from Israel and the International Phase-3-D project are under construction.

Details of these efforts and discussions concerning operations via the current group of operational hamsats were a significant part of the 1993 AMSAT-UK Colloquium. The meeting was held at the University of Surrey in late July and early August. Many well-known satellite designers and builders attended and presented papers detailing current and future efforts. Nearly 140 delegates from six continents exchanged views and stayed in touch with current findings and advancements relating to the new and future satellites.

Dick Jansson WD4FAB from AMSAT-NA detailed progress with the structural design of Phase-3-D. Viktor Kudielka OE1VKW described the causes for the eventual decay of

Photo C. Freddy De Guchteneire ON6UG and James Miller G3RUH demonstrated small dish for 2.4 GHz amateur satellite reception at the AMSAT-UK meeting. (WSIU photo.)

Figure 1. AMSAT certificate awarded for financial support of the Phase-3-D amateur radio satellite project.

Photo D. A close-up of the G3RUH Mode "S" receive system. (W5IU photo.)

AMSAT-OSCAR-13's orbit and the need for caution planning the path of Phase-3-D. Other noteworthy talks included one on radio astronomy, descriptions of the transmitters and receivers to be carried on Phase-3-D and Mode "S" (2.4 GHz receive) efforts by James Miller G3RUH.

Table 2 shows the new designations relating to satellite frequency bands to be used on Phase-3-D. The satellite will use a matrix of separate transmitters and receivers and thus does not call out transponders that use specific uplink and downlink combinations. Thus Mode "B" (70cm up and 2 meters down) would be

called Mode "UV" where the first letter describes the uplink and the second is the downlink. Innovative additions to Phase-3-D include a 5.654 GHz uplink, a 40 watt 10 GHz downlink, a new digital system called RUDAK-3 from Germany and a Japanese three-camera system with digital downlinks. All the transmitters for the new satellite are designed for much easier reception on earth.

James G3RUH gave a live demonstration of A-O-13 Mode "S" reception with his 60cm dish to show how easy microwave reception can be. A complete description of the construction of the small dish with

Figure 2. ARRL QSL sent in recognition of donations for Phase-3-D, sent via the American Radio Relay League.

helix feed was printed in the March/April issue of *The AMSAT Journal*. He also presented his 16-turn, 2.4 GHz helix used for direct A-O-13 "S" reception without a dish. Tests have proven that the small antenna is an adequate performer when used in conjunction with a low-noise preamplifier and a good converter system. James reminded those attending his talk that the effective radiated power at 2.4 GHz for A-O-13 is only 5 watts. Signals from Phase-3-D at 2.4 GHz should be somewhere between 5-20 kilowatts. This 30-36 dB signal increase means that the small helix is significant overkill. A quarter-wave whip (about an inch long!) should work just fine for Phase-3-D.

Support for Phase-3-D

All the incredible capabilities slated for Phase-3-D come at a price. This will be the largest, most comprehensive and expensive amateur radio satellite to date. The program needs money in addition to the donated parts and labor.

AMSAT-NA has been promoting

the project and raising funds for several years. A special contribution program based on yearly donations over a five year period started in 1991. With a minimum contribution of \$36.92, AMSAT will reply with a special Phase-3-D certificate with one sticker. Additional donations of at least \$36.92 each, bring more endorsement stickers to fill out the years from 1991 through 1995, when AMSAT hopes to launch Phase-3-D. AMSAT can be contacted via phone at (301) 589-6062 or by mail at 850 Sligo Ave. #600, Silver Spring MD 20910.

The American Radio Relay League launched a program in June with a mailing to all ARRL members briefly describing the Phase-3-D project and proposing an ARRL goal to raise \$300,000 from League members. Every contribution to Phase 3-D made through the ARRL is acknowledged with a unique QSL to serve as a permanent confirmation of support. The ARRL can be reached at 225 Main Street, Newington CT 06111. Be sure to mark any donations to the attention of Phase-3-D.

Magnet Circuit Correction

I hate to do this, but I am going to ask all of you to take your seats, get out your notebooks, and turn back a few sections to the notes you took on this column a few months ago. You didn't take any notes? Shame on you, now you'll have to go get the magazine itself. Why do I ask such a thing? Because there is a mistake in a schematic, and I don't want anyone tripping over it!

In the August 1993 edition of "RTTY Loop," I printed a selector magnet circuit designed by Bob Roehrig K9EUI. Unfortunately, somewhere along the line, a part of the diagram entered the great bit bucket in the sky. The corrected portion is shown in Figure 1. Without the missing resistors (R7 and R8), the keyboard will short out the 120 volt supply. So, get out your notes or magazine, and pencil in the correction NOW! You never can tell when you might decide to use this versatile circuit, and I'd hate to see you ruin a perfectly good power supply.

Digital Communications Terms

Moving right along, here's a letter from Bob Workman WA4ZZN of Atlantic Beach, North Carolina, which yifies the confusion which besets the ham entering digital communications. There are computer programs which simulate a TNC, and there are TNCs which require some kind of terminal, and there are terminal units which are needed by TNCs or programs to work. Bob needs clarification of this whole confusing mess of terms.

We need to begin somewhere, so let's start with some information encoded in digital pulses. These may be off a loop supply from a mechanical eleprinter or from a computer. These individual letters or characters need to be formed into the packets needed for packet radio communications. This is the function of the device commonly called a TNC, or Terminal Node Controller. Having formed those packets, the next step is to impress the packets of data onto a radio signal. This is done by some form of frequency shift keying, either audio frequency shift keying (AFSK) or radio frequency shift keying (FSK)—the former being used on VHF, the latter on HF. Reception is accomplished by receiving the frequency shifted signal, taking the audio output and converting it to on-off digital pulses through a demodulator or terminal unit, and then allowing our TNC to disassemble the packets and reproduce the desired communication.

Since conventional RTTY has no

need for packet assembly or disassembly, a TNC is not used for this mode, only a terminal unit for reception. Some of the terminal units which have gained popularity in recent years are the HAL Communications ST-5, ST-6, ST-5000, and ST-6000; Flesher TU-170; and many, many others.

While many hams use TNCs which are small circuit boards external to the terminal or computer, there are programs available for many computers which can create a TNC in software. For these systems, all you need is a radio interface, which may be affected by a terminal unit originally designed for RTTY only.

Conversely, there are many controllers on the market which integrate the TNC and terminal unit—let's call that a modem to more accurately reflect the transmit (modulate) and receive (demodulate) capability of these devices—into one box. Popular units from MFJ, Kantronics, and AEA can be seen in ads in this magazine.

Now, in the near future I hope to run information on modifying the Flesher TU-470 to run with some of the software TNCs. The clear answer is that it can be, and is being, done by many hams. This may well represent one of the most economical ways to get onto packet and, with some of the programs around, RTTY and even AMTOR, too! Thanks for the question, and good luck with the endeavor.

Model 42

Having corrected one, and answered one, now it's time to toss it out to you guys. I have a letter here from Eugene Matthews W0UAW from Topeka, Kansas. He writes, "I just acquired an almost new Model 42 Teletype (RO) machine, with power supply. I cannot find anyone who knows anything about this Model 42. I want to use this for hard copy. I need to know what connections to use to hook it up so it will print. Also, what current and voltage does this machine take to operate the selector magnets? The power supply is transistorized and must be 12 VDC output. What is the speed of this machine?"

Well, Eugene, the Model 42 is the end of the Baudot line, as far as I know. With a dot matrix output, it was able to accept TTL, current loop, or RS-232 interfacing. I believe that tape equipment was also available for this model. There was also a Model 43, which was the ASCII version of the Model 42. Buffered versions of this machine were available that could run at higher speeds.

I have no diagrams or specifics on the Model 42 or Model 43, but, somehow, I trust that someone out there in 73-land will share some with us, real soon! Watch future columns for the in-

Figure 1. Selector magnet correction.

formation, as soon as it surfaces.

Along those lines, folks, here's a question from me to all of you. I have been looking, very unsuccessfully, for the round, six-pin mike connector for my Satec HT-1200 transceiver to try to get it up onto packet. If anyone has located a connector, and wiring information for this antique, I would appreciate hearing from you!

Feel free to contact me for this, or any other related (or non-related) matter at the address above, or on Com-

puServe at 75036,2501, Delphi at MarcWA3AJR, or America Online at MarcWA3AJR. I look forward to your comments and questions, and yes, the various software collections are still available. Send an SASE for the list, or inquire via Email and I'll Email a response back to you. A look at that Flesher modification next month, and maybe a look way, way, back, too! Suspense? I can't stand it. Just don't let your subscription to 73 lapse! You might miss RTTY Loop!

AMATEUR TELEVISION

TVC-4G
only \$89

SEE THE SPACE SHUTTLE VIDEO

Many ATV repeaters and individuals are retransmitting Space Shuttle Video & Audio from their TVRO's tuned to Satcom F2-R transponder 13. Others may be retransmitting weather radar during significant storms. If it is being done in your area on 70 CM - check page 413 in the 91-92 ARRL Repeater Directory or call us, ATV repeaters are springing up all over - all you need is one of the TVC-4G ATV 420-450 MHz downconverters, add any TV set to ch 2, 3 or 4 and a 70 CM antenna. We also have downconverters and antennas for the 900 and 1200 MHz amateur bands. In fact we are your one stop for all your ATV needs and info. Hams, call for our complete ATV catalog - antennas, transceivers, amplifiers. We ship most items within 24 hours after you call.

More on the Boyd Sweeper

In the September column we looked at the Boyd Electronics RF sweep generator kit. This low-cost device provides CW, Symmetrical Sweep and Video modes. The CW mode operates like a regular signal generator, i.e. it outputs a single frequency for each setting of the 2-30 MHz frequency control. The symmetrical sweep mode is a variable-width swept frequency mode; the width of the swept portion is a function of the front panel settings. The video mode sweeps the entire HF range for every cycle of the sawtooth sweeping signal. In the original column I promised to discuss in the very next month's column add-on circuits that make the generator better. I didn't exactly lie, but other things came up that prevented me from putting that column together on time. This month, we'll keep that promise.

Three obvious improvements for any sweep generator project, including the Boyd unit are: an external step attenuator, a frequency translator for lower frequencies, and a marker generator.

The step attenuator is needed because the sweep generator outputs a rather large signal level . . . too large for easy testing of receivers and amplifiers in most cases. While the signal level will work well with some tuned circuits and filters, it is inappropriate for nearly any application that has amplification associated with it. A step attenuator (Photo A) provides switch-selectable levels of attenuation that can be in or out of the circuit as needed. In addition, the step attenuator will provide a swamping effect between the signal generator and the circuit under test in case the impedance of one or the other is not 50 ohms, or varies somewhat.

A frequency translator is needed because the Boyd sweep generator doesn't cover frequencies below 2 MHz. This limitation does not affect all hams because the IF frequencies in our HF rigs tend to be 8.83, 9.0 or 10.7 MHz . . . well within the range of the Boyd RF sweeper. But for those who need to sweep circuits below 2 MHz, including the once-standard 455 kHz IF frequency (used on Collins mechanical filters, even today), we need to be able to translate the Boyd sweeper's output to

a lower frequency. We need a double-balanced mixer (DBM) and a crystal oscillator.

The marker generator is a standard crystal oscillator that allows known frequencies to be injected into the circuit for the purpose of calibrating certain spots on the band. For example, if you use a 9.0 MHz IF in your receiver, you might want to have a 9.000 MHz crystal oscillator to mark the spot on the oscilloscope presentation of the sweeper signal.

Step Attenuator

A step attenuator such as Photo A consists of several stages of pi-pad resistor networks, each of which can be switched into or out of the circuit with a DPDT switch or relay (Figure 1). Table 1 shows the values of resistors needed in the pi-attenuator for various popular levels of attenuation. Alternatively, if you want the attenuator to be a little more precise, then use Mini-Circuits AT-series fixed attenuators. These devices are designed to fit onto printed circuit boards and perf boards on the standard 0.100-inch center holes. The type number, AT-x, is formed by replacing the "x" with the level of attenuation desired; e.g. AT-1 is 1 dB, AT-6 is 6 dB, AT-10 is 10 dB, AT-12 is 12 dB, and AT-20 is 20 dB.

In order to obtain higher orders of attenuation, one need only series connect several lower order stages. For example, to obtain 40 dB attenuation, cascade two 20 dB attenuators, or a 20 dB and two 10 dB attenuators.

In some cases, you might want to use a barrel attenuator. These attenuators are in-line, fixed attenuators that have a male coaxial connector on one end and a female coaxial connector on the other. They can be placed anywhere in the transmission line from the signal source to the circuit under test, although in most cases the preferred location is right at the signal generator output. The attenuator male connector is attached to the RF output connector of the signal generator, while the coaxial transmission line to the load is connected to the female connector on the attenuator. These devices are also available from Mini-Circuits, but at somewhat higher cost than the printed circuit variety.

One thing that you must do when building a multistage step attenuator is to use real good shielding between successive stages. Any signal leakage

around the circuit detracts from the attenuation value selected. The ARRL Handbook for Radio Amateurs for most years has an attenuator project. In one version of that circuit, pieces of copper-clad printed circuit blank material is used to fashion the walls and sides of the step attenuator compartments . . . and only one stage is inside each compartment. You can also use brass stock from hobby shops to fashion the walls and sides of the step attenuator compartments . . . and only one stage is inside each compartment. You can also use brass stock from hobby shops to fashion the walls and sides of the step attenuator compartments . . . and only one stage is inside each compartment. You can also use brass stock from hobby shops to fashion the walls and sides of the step attenuator compartments . . . and only one stage is inside each compartment. You can also use brass stock from hobby shops to fashion the walls and sides of the step attenuator compartments . . . and only one stage is inside each compartment.

Frequency Translator

A frequency translator to make the RF sweeper work below 2 MHz is relatively easy to build. The Mini-Circuits (P.O. Box 350166, Brooklyn NY 11235-0003) passive double-balanced mixers such as the SRA-1, SBL-1 and SBL-1-1 are easily obtainable, and well-behaved (i.e. they do what they are advertised to do). We've discussed these devices in this column previously.

You can also use the Signetics NE-602 double-balanced mixer IC device for the translator. The NE-602 contains a Gilbert transconductance cell DBM and a local oscillator stage, and has been covered previously in these pages.

Four features are needed to make the translator work in this context: a mixer device, a crystal oscillator, a high-pass filter terminated into a 50 ohm dummy load, and a low-pass filter that carries the output signal. The filters are necessary because the output of the DBM will be the sum and difference of the RF sweeper and crystal oscillator signals ($F_1 + F_2$ and $F_1 - F_2$). The sum frequency is not needed, so it is passed through a high-pass filter to be absorbed in a 50 ohm dummy load (actually, a 51 ohm resistor will do). The difference frequency is passed through the low-pass filter to a 50 ohm output terminal. It is probably smart to use a matched amplifier at the output of the low-pass filter because the mixer and the low-pass filter have insertion losses associated with them, and an amplifier

Figure 1. Switchable attenuator stage (see Table 1 for values).

will make up for that loss.

Figure 2 shows a circuit that can be used for this purpose. The RF sweeper input signal is fed to pin no. 1 of the DBM, which is its RF input. This signal must be kept below +1 dBm or the mixer might suffer harm. A series -3 dB attenuator is used to reduce the signal level. Even if the signal level is below the +1 dBm level, some people like to use the attenuator anyway because it provides a "swamping" effect against impedance variations. In those cases, a 1 dB attenuator can be used. Keep in mind that, for situations where the impedances are constant and the signal level is within range (below +1 dBm), the attenuator is optional.

The local oscillator circuit is a standard crystal oscillator circuit with an output amplifier to boost the signal level. Ordinary NPN silicon transistors can be used (2N2222, 2N4401, 2N3904, etc.) The mixer likes to see local oscillator signals in the +7 dBm range for proper conversion, which means, at 50 ohms, 5 mW power level or a peak-to-peak voltage of 700 mV. The crystal chosen can be anything in the 2 to 10 MHz region, so long as you can adjust the sweep generator to be within the difference frequency of the lowest sweep generator output frequency. I chose a 6 MHz crystal because it is one of the standard "microprocessor clock" crystals available at low cost from local parts sources. Crystal suppliers can make any exact frequency you need, or you can use one of the computer clock standard frequencies, or a 3.579 MHz color TV "color burst" crystal . . . all at low cost.

The output filters can be easily made from toroid coil forms or, if you prefer, standard coils obtained from parts suppliers. If you opt to use the toroidal cores, then use T-50-2 (RED) cores. These devices have an AL value of 49, so the following turns counts will suffice:

L1,L2	3.14 μ H	25 turns
L3,L5	4.9 μ H	32 turns
L4	8.5 μ H	42 turns

The capacitors in the filter should be either silver mica or NPO ceramic devices, with the latter being preferred over

Photo A. Commercial step attenuator.

Motorized Beams, Santa Barbara Style

One reason that VHF hidden transmitter hunting is a growing activity for ham clubs is that it's inexpensive to get started. You can go on foxhunts or T-hunts (as these events are called) with the 2 meter radio you have now, if it has an S-meter.

A quad, yagi, or other radio direction finding (RDF) antenna is cheap, especially if you make it yourself from PVC pipe and wire or from scrap TV antenna tubing. Add an RF attenuator made from some toggle switches, carbon resistors, and copper-clad board, mount the beam on your car, and you're set. Such a setup is more than adequate to win many hunts, with practice.

However, like participants in any other sport, T-hunters are always looking for an advantage over the competition. Decades ago, they discovered that a polar display of signal strength versus direction gives a much better

Radio Direction Finding

understanding of signal characteristics than an S-meter alone, particularly when hunting among tall buildings or hills that bounce and scatter 2 meter signals.

"Homing In" covered theory and advantages of polar displays in detail with actual trace photos in October 1992. KK6CU's home-brew mobile implementation of the scheme was featured in the following issue, complete with motorized quad and storage scope indicator. Now two T-hunters from Santa Barbara, California, have found a way for penny-pinching tinkers to have a polar display and motorized beam without the expense of a storage monitor and the hassle and noise of RF slip rings.

Look! No Slip Rings!

Tom King KA6SOX works in marine electronics at the Santa Barbara harbor. Kerry Provancha KK6OS enjoys mechanical engineering challenges. Together, they created the RADAD, which stands for "Radio Detection And Direction" (see Figure 1). As passers-by admired it at a recent ham radio swap meet, I interviewed them and

Photo A. Kerry Provancha KK6OS brought the RADAD to the TRW swap meet and unscrewed the covers to reveal the antenna turning mechanism.

they eagerly told me how it came about.

KK6OS: "We were looking for a long persistence phosphor cathode ray tube (CRT) display, rather than a storage scope, because a storage scope needs to be cleared all the time."

KA6SOX: "I happened to get some junk marine radars. The magnetron transmitting tubes had croaked or the high voltage boards had gone up in flames. They're economically unrepairable for marine service because I

can't get tubes or power supplies a reasonable cost. Fortunately, those parts aren't needed for RDF."

KK6OS: "Of course, the microwave transmitter, receiver, and horn antenna were of no use, but we retained the rest of the radar essentially intact. We changed the antenna drive motor because we wanted different rotation speeds (see Photo A)."

KA6SOX: "Sometimes we want to paint the RDF picture slowly and sometimes fast, depending on what the hider is doing. So we used a 31

volt DC motor and built a variable voltage inverter to control speed."

KK6OS: "It's difficult to find motors with adequate torque over a wide speed range. We use a DC gearhead type about 5 inches long, about 100 rich-lbs. torque."

KØOV: "How did you make the 'adar scope show 2 meter bearings?'"

KA6SOX: "It was very simple. All the CRT power supply and sweep circuitry is already there (see Photo B)."

KK6OS: "The electronic yoke in the display follows a resolver, which is geared to the antenna (Photo C). Whatever speed the resolver goes, the yoke on the CRT follows exactly. There is no mechanical stuff in the yoke."

KA6SOX: "As the antenna turns, the yoke sweeps the CRT electron beam in a circle. In addition, the radar control head generates a linear voltage ramp that sweeps the beam from

screen center toward the edge at about 200,000 times per second."

KK6OS: "We compare receiver S-meter voltage with the ramp voltage. The comparator triggers a one-shot to produce pips, replacing the radar pulse. It pulses the CRT cathode negative for 1.5 microseconds. The S-meter voltage compared against the ramp determines how far out on the screen from the center you get pips. The resolver tells where on the azimuth circle to put the pips."

KØOV: "So at 200,000 pips per second, it looks like a continuous line is being drawn on the screen."

KA6SOX: "Right. Full scale on the S-meter equals maximum deflection to the edge of the screen. The interface was done with one LM339 quad op amp IC."

KØOV: "What about your antenna design?"

KA6SOX: "We went through about a half dozen iterations of the antenna."

KK6OS: "We tried to make one that would fit inside the radar's plastic radome so there would be no wind-loading. But it was a negative gain antenna without a decent pattern. It would probably work on 450 MHz, but not on 2 meters."

KØOV: "So you made a full-sized 2 meter beam to get good sensitivity?"

KA6SOX: "Yes. We solved the rotary joint problem by using an AEA half-wave whip antenna as the fixed-

mounted driven element. The directors and reflectors rotate around it. It gives a beautiful pattern."

KK6OS: "There are no slip rings. The driven element mounts on a BNC that never rotates, so it's noise-free (see Photo D). The coax goes right up through the center of the waveguide where the radar output used to be. The antenna is a three-element yagi, made of a PVC pipe upright and crossbar. Two directors and a trigonal reflector rotate around the driven element. It's all painted stealth black and sits on a rack that bolts to the car-top carrier (see Photo E)."

KØOV: "Was the trigonal reflector used for a better pattern or for mechanical balance?"

KA6SOX: "Both. We had a single reflector at first. When we changed to the trigonal reflector, the lobes on each side dropped by 5 dB and the back lobe completely disappeared. We measured 0.7 dB more gain, too."

KK6OS: "Now the antenna was mechanically balanced almost perfectly."

KA6SOX: "But we discovered that mechanical balance is not the same as windload balance. Even with the triple reflector, when we were going down the road at 40 MPH, it would stall. We then added a small fin on the back. Now we can drive up to 55 MPH with no problems."

KØOV: "How do you shrink the display size as you close in?"

CIRCLE 234 ON READER SERVICE CARD

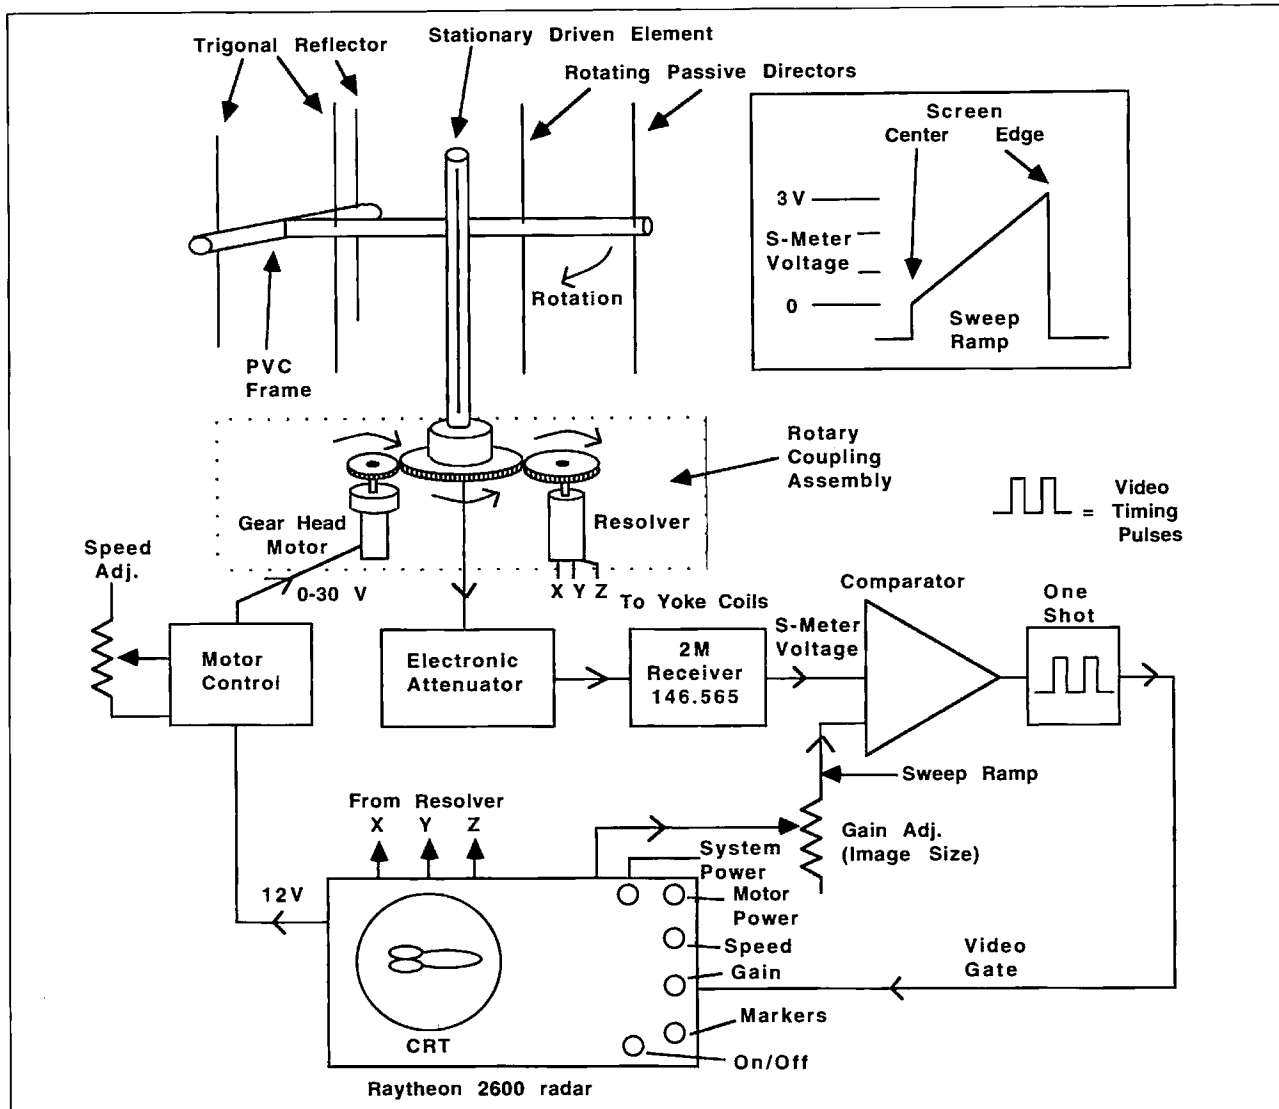

Figure 1. The RADAD is made from a defunct marine radar display unit and rotary coupling assembly, added to a 2 meter receiver, attenuator, and PVC pipe yagi.

KA6SOX: "With an RF attenuator. It's based on the offset attenuator in QST for November 1992. We changed

the offset to 1 MHz and use a crystal-controlled oscillator, plus better shielding."

KK6OS: "The continuously variable electronic attenuator has been the biggest single improvement to the whole system. It makes it easy to keep the display on screen. Before that, we used a switchable resistive attenuator, which was hard to use because of the large step sizes."

KØOV: "Tell me about hunts in Santa Barbara."

KK6OS: "We have all kinds, including mileage hunts (lowest odometer miles wins), time hunts (first finder wins), and combination time/mileage hunts. The hider decides. Most are time-only. We hunt on the fourth Saturday night of the month on 146.565 MHz."

KA6SOX: "A few months ago, the hiders wove the antenna inside a volleyball net at the beach. They used RG-174 coax, painted the color of the volleyball tape along the bottom. It was then painted yellow along the pole all the way down into the sand, where the transmitter was buried, running about 50 watts. I'm pretty sure

the vertical pole was a non-tuned reflector. We found the general area easily, and the hiders were sitting right there roasting wieners. The big problem was finding the antenna and the radio."

KA6SOX: "Some T-hunts in Santa Barbara have become absolutely insane. They're not like Los Angeles All-Day hunts, where the T is miles and miles away. But dirty tricks by the hiders are allowed. They do all kinds of weird things, like swinging beams and hiding multiple T's."

KK6OS: "I started it, I guess. On one hunt, we synchronized two transmitters. When one came on, the other one went off, and so on. They were on two different mountaintops. We were trying to screw up the Doppler users so they would get an indication that went this way, then that way. My former T-hunt partner has the control box for the synchronized T's and he likes to use it. Other hams have come up with their own schemes for doing it too."

Photo C. The 30 VDC motor is geared to the rotating antenna mast and the resolver. Inside the mast is the old waveguide, which holds a stationary driven element.

Photo D. Marine radar technician Tom King KA6SOX has taken off the yagi frame with parasitic elements and is holding the top of the driven element whip.

Photo E. This lightweight vertical yagi with trigonal reflector has good gain and an excellent pattern, yet spins up to 140 RPM while the car moves at 55 MPH.

KA6SOX: "Sure, but who knows how many are still in service and how many are at the bottom of the ocean! They have longer service life than most radars of the '70's because they don't have a rotating yoke assembly to fail. There are probably 35 or 40 still in use on the thousand or so boats in Santa Barbara harbor. I saw a used one being installed on a boat about three weeks ago."

Let's Try It

After the swap meet, I rode along as Tom and Kerry demonstrated the RADAD on a beginners' hunt sponsored by the TRW Amateur Radio Club. The system worked smoothly and quietly, giving excellent scope patterns. In just a few minutes, we arrived at a parking lot where the hidden signal was super-strong.

None of us had brought "sniffing" equipment, so I tuned to the third

harmonic of the hidden T signal with my dual-band handheld, got a bearing by body shielding, and started walking. Five minutes later, I tracked down the antenna 15 feet up in a tree.

Tom and Kerry have found a simple, yet elegant scheme for feeding a continuously rotating beam. Waterproofing is easy and there are no slip rings to make noise or cause losses. The main disadvantage is that only vertically polarized yagis can be fed in this manner, a problem in areas where hiders are allowed to use horizontal polarization.

You can't buy a RADAD, but if you're a knowledgeable builder, you can assemble a similar system. With careful scrounging, you'll preserve your T-hunting gasoline fund. It's time to hit the swap meets and make friends with your local marine electronics tech!

73

K0OV: "Have you won any hunts with the RADAD?"

KK6OS: "I won with it in June, so I hid in July. When I hid, I used the spinning RADAD antenna in a parking garage downtown. I set the antenna unit on the floor at a middle level of the garage, rotating at 20 RPM. I transmitted 5 watts SSB modulated with a pulsed 500 Hz tone, a quarter second on, then a half second off. I was trying to make the Doppler RDFs go wacky. It didn't do that, because one guy found us in 15 minutes. But another hunter ended up dozens of miles away in the wrong direction from he start, and three teams gave up without finding it."

K0OV: "So your system does a great job finding tough T's, right?"

KA6SOX: "It's still experimental. We don't consider it to be a breakthrough, but it's quite a step forward in distinguishing what is a signal reflection and what is not, which the Doppler cannot do when the two are equal in level. However, it requires a skilled operator to interpret it."

KK6OS: "Up here in Santa Barbara, hunters often pulse the signal. If they flicked just the right pulse rate and our antenna was going at just the wrong speed, the CRT screen became useless. On a couple of hunts, I was pulling my hair out. I could not get a bearing, because they were pulsing exactly three times for every rotation of the unit. Since then, we changed the motor control to cover 0 to 140

RPM. With the long persistence P7 CRT at night, you can see 15 to 20 traces superimposed at 140 RPM."

K0OV: "What radar models do you recommend for readers who want to make their own RADAD?"

KA6SOX: "Models 2600 and 2800 are the best. Raytheon designed and imported them, but they were made by Japan Radio Corporation. They're also known as the Mariner's Pathfinder. They were produced between 1970 and 1976. Raytheon sold 35,000 of the 2600s worldwide, and around 8,000 of the 2800s.

K0OV: "Are these radars available?"

The Invention Connection

In the July 1992 edition of *73 Amateur Radio Today*, I wrote a column called "Invention Versus Innovation." I discussed different techniques a teacher can use in the classroom to help children develop inventive thinking skills. Amateur radio in the classroom allows the teacher to bring out the very best in creativity and analytical skills in the students. I received an excellent response to this column from other teachers who shared their experiences with me after following some of the suggested activities.

One of the interesting letters I received was from William L. Enter, Sr., KB5NUA, founder and past president of the "Invention Development Society, Inc." He points out that inventing is a prized human trait. It sets one apart from others in a unique way. Few people develop their ideas to the practical stage and still fewer to the patenting stage. Congress created the Patent

Office in 1836, yet the five millionth patent was granted only last year.

William holds three U.S. patents and has invented at least 58 electronic circuits. He says there are many opportunities for young minds to benefit from an invention program. "We could use some new electronic circuits," says William.

He has been working with the Oklahoma Student Inventors Exposition since April 1982. This program is designed for grades K-12. Statewide participation has annually been as high as 4,428. The organization teaches teachers how to teach thinking skills and problem-solving skills to their students. The students learn to do analytical thinking and creative problem-solving on a daily basis in all subject areas. The children are then required to research their community for an unmet need and to invent something which serves that need. They must produce a novel response that solves the problem at hand. Their inventions must be a simple, elegant, aesthetic solution to a real everyday problem. Kindergartners tend to do better than 12th graders. I'll bet that most of the teachers reading

Photo A. Richard Starks, 1990 Grand Prize Winner, shows "The Stick-Um Fly Swatter."

this column recognize why that is so. One of the necessary traits to being truly creative or inventive is to have a mind-set that is basically uninhibited. Younger children seem more apt to have that.

There is a National Creative and Inventive Thinking Skills Conference every year, held in a different city each time. If you would like more information about the conference or about the

Oklahoma Student Inventors Exposition, contact Ms. Betty Wright at (405) 670-3131. She is a Regent for Osca Rose State College in Oklahoma City and has a TV show called "Mail Counts." She teaches gifted and talented children in the Oklahoma City schools. The "Guidelines" brochure for the contest is free to Oklahoma teachers; \$1 postpaid for out-of-state orders. There is a price reduction for 10 or

Low Power Operation

Michael Bryce WB8VGE
2225 Mayflower NW
Massillon OH 44646

Small, crystal-controlled transmitters like the Ryan Communications exciter described the other month are great fun. Crystal control does have one drawback, however: You're stuck on one frequency.

At first I was working on a simple VFO for the Ryan exciter. After a few days on the bench, my simple VFO became rather complex. My Ryan exciter is on 30 meters, so the need for a wide frequency swing seemed like overkill. A better, and perhaps simpler, way to move around the 30 meter band was to swing the crystal's frequency—a VXO. The Ryan exciter's oscillator will not allow VXO operation as is, so I tried several different variable capacitors in series with the crystal, with lackluster results. I then tried building a completely new and different oscillator on a small piece of perfboard. I really did not want to make major changes to the Ryan exciter, so I built a second board containing the VXO.

The oscillator is broadband, thanks to T1. An 2N5179 will develop more than enough umph to drive the Ryan exciter. If you don't have a 2N5179, a metal case 2N2222A will work fine, too. The output of Q1 goes to the broadband transformer T1. The primary of T1 con-

sists of 20 turns of #26 enamel wire on an FTP37P43 core. The center tap is at 13 turns from the collector end of T1. The secondary has four turns of #26 wound over the entire core. Don't bunch this secondary winding all up on one end of the core—spread the turns over the entire core.

The resistors on the output of T1 place a slight load on the oscillator. A 0.01 μ F capacitor couples the output from the oscillator into the Ryan exciter.

You can use any variable capacitor for C1 as long as you don't go over 50 pF. Use a good quality capacitor for C1 as you'll be running it back and forth through its range a great deal. A double-bearing capacitor would be grand, but they are kind of hard to find. Check with KA7QJY Components (P.O. Box 7970, Jackson WY 83001) for his list of variable capacitors.

The crystal used for the VXO should be a fundamental crystal in an HCP25/U holder with a parallel resonance of 20 or 30 pF. Don't get high tolerance crystals—tolerance of 0.01% is fine for the VXO. Crystals mounted in the FT-43 holders do not work well with VXO circuits.

There are two methods of getting the oscillator to talk to the Ryan exciter. Either one will work, and both require some changes or additional circuitry to work.

The best method is to re-work the

crystal oscillator of the Ryan exciter to work with the new oscillator. I tried to couple the new oscillator into the base of the Ryan oscillator. This will work if you're really into milliwatts (I was only able to get about 300 milliwatts from the exciter).

To get full exciter output you'll need to change some components in the Ryan oscillator. The first step is to change the 820k resistor on the base of the oscillator transistor, 2N4124, to 10k. Remove the 270 pF capacitor from the base of this transistor, too. These two changes now make the oscillator on the Ryan exciter into a buffer/amplifier. You can still key the exciter as usual by grounding the emitter of the 2N4124. Connected this way, the output of our VXO, coupled to the base of the 2N4124 on the Ryan exciter, will provide operation exactly like a crystal-controlled exciter.

There is one catch in running the VXO and Ryan exciter this way: You have to keep the external VXO running all the time. You key the Ryan exciter by grounding the emitter lead of the 2N4124. This normally keys the crystal oscillator. Since we've changed the oscillator into an amplifier, the external VXO must run continuously. There are two fixes to this problem. First, just key the Ryan as usual and let the VXO oscillator run all the time and remove power to it during receive. Or, you can short the key line on the Ryan exciter and key the VXO. To key the VXO, you'll need to add a keying transistor in series with the VCC line. A simple 2N3905 will suit the bill here. I went into a bit of overkill and

used a 2N4037 to key the VXO.

Since you may have to add the keying transistor to the VXO oscillator, you can then use a second method of coupling the output of the VXO into the Ryan exciter without swapping out parts. Simply couple the output of our VXO oscillator into the Ryan exciter directly to the driver transistor. Add the VXO drive directly to the base of the 2N5089 driver on the Ryan exciter. When you do this you must key the VXO as the driver will amplify whatever it sees and pass it to the final. You can key the VXO oscillator and you don't have to mess with the Ryan exciter except for one shielded cable from the VXO.

Add an Amplifier

Because you'll not have the benefit of the extra stage of buffering between the VXO oscillator and the driver stage, you may want to add a small buffer amplifier. I have not tried this but it seems like a good idea. The schematic shows such a circuit taken directly from the *QRP Handbook* published by the ARRL.

This is an easy project to build on perfboard—a PC board isn't necessary. Just keep component leads short and direct. Test each circuit before you start on the second one. Be sure you have the Ryan exciter running on a crystal before you start removing parts from its circuit board. Remember, when your soldering iron hits the PC board of the Ryan exciter, the warranty goes up in smoke.

There you have it. VXO operation for the Ryan exciter. This will really bring out the QRP bug now that you are no longer rock-bound.

MODEL 43

Thruline Directional Wattmeter—

The worldwide standard in directional wattmeters.

- Accurate within $\pm 5\%$ of full scale reading.
- Measures forward or reflected power in coaxial transmission lines under any load condition.
- Power range from 100mW to 10kW. frequency range from 0.45 to 2300MHz.
- Utilizes Bird's "QC" quick change connectors for interchangeable field operation without recalibration.
- Built-in remote-reading capability.
- Peak reading version available.

Getting Started in TCP/IP, Part 2

Last month we started a series of articles on TCP/IP over ham radio, including how to do it. The first installment explained what TCP/IP is, and why it has advantages over the more familiar AX.25 "packet" protocol that most hams use. This month we'll talk about what you need to set up a working TCP/IP station and where to get it.

TCP/IP (Transport Control Protocol/Internet Protocol) is a way of moving various sorts of data in various sorts of packages. Associated with IP are a number of protocols for moving mail, bulletins, and data less—as well as ways of connecting or real-time discussions. We'll explore all of these in this series. First, of course, you need to be able to connect to the world of IP. What do you need to do this?

The "normal" packet radio protocol (AX.25) is usually built right into the hardware that a ham buys for "packet." The TNC (Terminal Node Controller) has a small processor and some firmware in ROM (Read Only Memory) that can talk right to a dumb terminal and radio. All that is needed to connect the pieces together with the appropriate cables and the station on the air.

While TCP/IP uses pretty much the same pieces as an AX.25 station, the bits get switched around a bit. Though the AX.25 station frequently employs a computer as the dumb terminal, it doesn't need to. Anything that can "speak" RS-232 will work. For an IP station, though, the computer takes over most of the "thinking" from a TNC. The IP software puts the VC into KISS (Keep It Simple, stupid.) mode and handles all of the protocol business.

The Computer

Just how much machine do you need to run IP? The answer to this question varies a great deal, depending upon what you intend to do. TCP/IP stations run the gamut from single-user setups that only operate clients—users of other stations—to full-blown multi-service hosts (PBBS). Nearly any computer is capable of operation in the first category. Variations of NOS (the original TCP/IP software from Phil Karn's KA9Q) are available for just about every personal computer, and for UNIX on many platforms. Because of the overwhelming likelihood that you are using an MS-DOS-based computer, that is what we'll concentrate on. However there are also versions for the Amiga (another popular computer among hams)

readily available. In addition, the program we will discuss most—JNOS from WG7J—is available in source code form. If you can use a C compiler, you might just be able to whip up a version for your own machine.

NOS and its variations are designed to be multitasking. That is, they run several processes simultaneously. In practice this means that there are separate, tiny programs doing a variety of things—apparently—at the same time. Since there is only one processor in your machine, what is really going on is a time sharing affair. Process 1 uses the CPU, then process 2, then maybe process 3 or even 1 again. From the user level the events that result from these processes appear to occur at the same time.

All this activity requires as much memory as it can get. Unfortunately, the versions of NOS that you can get today are not capable of using extended or expanded memory. They will use as much of the first 640K as you can give them, though. So, the first requirement for the IP station PC is 640K base memory.

As you might have guessed, multitasking is very CPU-intensive as well. This means that an IP station PC will be happier with a faster CPU. The simple rule is: The faster the better. Slower CPUs will produce various sorts of errors when they are loaded down with IP activity. Remember that the IP station must listen to you and the radio at the same time as it does its housekeeping. The station's use determines this load. A full-service host will run reasonably well on a 286/12 computer, but much better on a 386/25.

The programs and data files needed to run NOS are not that large. You could conceivably run an IP station on a floppy-based machine. On the other hand, even a small hard disk is a big improvement. Also, if you intend to run a full-service host, you will probably want to offer files for FTP (File Transfer Protocol) download. You'll need someplace to keep these.

The TNC

A TNC for IP station use does not need to be anything special. Basic IP operations at 1200 baud on VHF/UHF can be done with any TNC that offers KISS mode operation. The least expensive boxes, like the PK-88 from AEA, do just fine at this. However, if you are in a high activity area, or want to run a full-service host on a "backbone," you'll want to consider fancier options.

Most activity in the digital ham radio world today runs at 1200 baud. This is the normal data rate for AX.25, and is standard on just about every TNC you can buy. Higher data rates are generally more desirable, but 1200 is entrenched. The backbones, though,

usually run at 9600 baud or faster. There is a trend to faster user port speeds with a considerable contingent proposing a just right to 9600 baud. How does this affect your choice of TNC? Just keep this in mind, and think about something that can be upgraded to a higher speed, even if you don't do it now.

The Radio

As far as radio choice is concerned, IP adds nothing to the requirements. A good choice for packet is a good choice for IP. When looking for a radio, keep these requirements in mind:

Choose something modern. While a used radio is just fine, it should be a newer model if possible. Digital radio requires the radio to switch from receive to transmit very frequently. The delay in going between modes is called "switchover" time. This delay needs to be as short as possible to ensure good performance.

Choose something powerful. Though you can use a handheld for packet or IP, it is a risky proposition. For a radio LAN (Local Area Network) to work right, every station (called a node in LAN terminology) must be able to hear every other. With a low-powered station on the net, disruption and unreliable connections are likely. The power requirement varies with the particular LAN. The further the nodes are spread geographically, the more powerful the transmitter needs to be. If you are thinking about using an amplifier on a handheld, consider this: It may not switch fast enough to work at higher speeds. While even COR (Carrier Operated Relay) style amps usually work at 1200 baud, at higher speeds the switchover time of many amps will be too long.

Choose something sensitive. This is just the flip side of the powerful requirement. A sensitive receiver will help to improve the station's performance on the LAN.

Choose a good antenna. With good "ears" your receiver and transmitter will operate more efficiently. You need an omnidirectional antenna, NOT a beam. Remember, all the other stations have to be able to hear you for things to work right. A beam is only appropriate in a limited number of cases. Put the antenna up as high as you can and use good coax—remember that loss goes way up with frequency.

The Software

The rest of the articles in this series will discuss installing, configuring, and maintaining JNOS—a full-service variation on KA9Q NOS. The executable is for MS-DOS-based machines, and is frequently updated by the author, Johann WG7J. I chose to use this implementation for several reasons:

It is popular.

It is widely available.

It has a stable working version with very few bugs.

It has all the features needed for a full-service host.

It will work as an Internet gateway.

It has a reasonably good user interface.

I am using it here.

JNOS offers all of the host and client services currently available for amateur TCP/IP. For the end user, it offers a decent user interface, a split-screen terminal for AX.25 connects, POP mail (more on this later), and up to nine concurrent sessions with hot key switching. For the PBBS operator, JNOS offers superb mail connectivity (normal packet mail plus SMTP and POP servers), excellent security.

My choice of JNOS should not be construed as disparaging to any other NOS implementation. There are lots out there, and all have strengths and weaknesses. Each implementation is slightly different, so I had to choose just one. If you have a machine for which JNOS is unavailable, don't fret. You can get the source and compile a version—or you can find something else that works. While another implementation will not be identical, above the detail level you will still find the information presented here useful.

Getting JNOS

We will be working with JNOS version 1.07b. I will offer two ways to get it but, with a little ingenuity, I am sure you can find it elsewhere. First, if you have anonymous FTP access to the Internet, you will find the MS-DOS executable and source at:

ucsd.edu

In the directory:

\hamradio\packet\tcpip\jnos

The files are:

jnos107b.exe (executable)

jnos107b.zip (source)

jnosdoc.zip (documentation)

Get the executable and documentation files. If you want to compile a special version, get the source. (NOTE: If you don't know what "FTP" is, don't worry—just go on to the next option.)

The second way to get the files is from the 73 BBS. Be warned that the BBS can only do 2400 baud, so this will take awhile. The 73 BBS can be reached at:

603-924-9343 (8N1)

When you connect, follow the instructions and provide the requested information. When you get to the main menu, choose "F" for file area, and "9" for packet. The executable and documentation will be there.

Next Month . . .

. . . we'll actually install the software and start to configure it. While it is not a trivial operation, I imagine many of you will be on the air at that point. In the meantime, you might just try getting on the air without my help. Don't let it frustrate you: The docs can be confusing and the setup is not intuitive. Good luck! 73 de N1EWO

The N8EWV R/C Plane

Thanks to the ever-shrinking size of ATV transmitters and TV cameras, a number of enterprising ATVers have been successful in flying their systems onboard modest sized R/C aircraft. This month I'd like to share some of the innovations that Larry Hillier N8EWW of Beloit, Ohio, has designed into his R/C ATV plane.

Starting out with plans for a Hobby Lobby Telemaster (eight-foot wingspan), Larry built his plane from scratch, eventually adding wing tanks (half-gallon fuel capacity) to his current plane to allow for extended flight. The original model was powered with a four-cycle Enya 120 engine, but has been replaced with a 1.6 hp Zenoh 23 two-cycle gas engine (essentially a converted chain saw engine). This new engine allows him to use an inexpensive gas/oil mixture instead of the very expensive glow fuel common to most R/C planes.

The ATV Section

Larry installed most of the ATV equipment in the rear of the plane. His system consisted of a P.C. Electronics TXA5-RC 1 watt transmitter, an FMA5 audio subcarrier board and a Canon UC-1 color camcorder. The camcorder was placed just under the wing in the cockpit, facing out the side window. Larry can control the viewing angle of the camera through the use of a servo which moves the camera from the horizon to about a 45-degree down tilt. Since he uses a Futaba six-channel PCM R/C controller (50 MHz band), he had some extra channels to control the camera angle and to turn the ATV equipment on and off remotely.

Airborne Simplex Repeater

In addition to his ATV station, Larry put an ICOM 2AT and a U.S. Digital simplex repeater controller in the front section of the plane. With 32 seconds of recording capacity (in the high quality audio mode), the plane now acts as an airborne repeater during each flight. Since the simplex repeater is set up on the ATV calling frequency of 144.340 MHz, this works well in alerting area ATVs that the airplane is up and flying.

Larry has had some very long-range contacts using the plane as a repeater. Several stations as far away as West Virginia (over 100 miles away) have worked through the plane during some recent flights. Since there was some confusion as to the operation of a simplex repeater, Larry now operates the repeater with an output on 144.34 but has the input 600 kHz up on 144.94.

The Antenna System

Since he has a variety of transmitters onboard the plane, Larry had a real challenge deciding where to place his antennas to reduce interference to his R/C receiver. He finally mounted an Old Antenna Labs Mini-Wheel antenna (omni-horizontal ATV) under the plane just below the tail. The 2 meter antenna consists of four radials strung along the fuselage and into each wing. The driven element is a 5/8-wave length of piano wire that dangles just below the landing gear. This flexible piece of wire simply scrapes harmlessly along the ground during takeoff and landing, but pops out directly under the plane during flight.

After providing the maximum separation for the antennas, Larry mounted the two transmitters and the R/C receiver as far apart as possible. He also shielded the R/C receiver. The final configuration had the ATV transmitter in the tail of the plane, the R/C receiver in the middle and the 2 meter simplex repeater in the front. He can now fly

the plane so far from him that it is a mere speck in the sky without any loss of control due to interference.

Long Duration Flights

Larry often flies his R/C ATV plan right around sunrise and sunset. He has received numerous reports of excellent video from stations all over northeast Ohio. Many of the reports come in via the onboard simplex repeater. There's nothing like creating your own 500-foot tower to increase your ATV range!

Now that he has a half-gallon fuel tank, he can fly for upwards of 1.7 hours. His most recent duration attempt flew for 1-1/2 hours and he still had 2 ounces of fuel left! At the end of September (the month this column was written), Larry plans to fly his plane over a 60-mile path from near Warren, Ohio all the way up to the shore of Lake Erie. He will follow along underneath the plane while riding in the back of pickup truck with a TV set and R/C transmitter. He plans to keep the plane in sight (both visually and via ATV) throughout the flight. Since the plane is capable of 55 mph airspeed, there should be more than enough fuel for the whole flight.

Larry is planning another R/C AT plane. This one will be a seaplane with the engine mounted above the wing. There will be a movable nosecone that will contain the TV camera and will allow the camera to pan up and down (similar to the Concorde's nose sensor).

ion). The camcorder controls will be remotely controlled via fiber optic lines or a touch-tone decoder, so that all functions including zoom can be operated from the ground.

The KD8PE ATV Repeater

If you are traveling through north-eastern Ohio and would like to talk with Larry N8EWV about his ATV plane, you can usually find him, as well as the

local Youngstown/Salem, Ohio, ATV group, working through the KD8PE ATV repeater during their weekly ATV net every Thursday evening at 9 p.m. local time. The KD8PE ATV repeater is located on a 190-foot tower

in Beloit, Ohio (439.25 MHz input/426.25 MHz out). They use 144.34 MHz for their ATV talk frequency. Also, a number of the ATVers in the area monitor the high profile 146.865 (-600) repeater.

Snow free line of sight DX is 90 miles - assuming 14 dBd antennas at both ends. 10 Watts in this one box may be all you need for local simplex or repeater ATV. Use any home TV camera or camcorder by plugging the composite video and audio into the front phono jacks. Add 70cm antenna, coax, 13.8 Vdc @ 3 Amps, TV set and you're on the air - it's that easy!

TC70-10 has adjustable >10 Watt p.e.p. with one xtal on 439.25, 434.0 or 426.25 MHz & properly matches RF Concepts 4-110 or Mirage D1010N-ATV for 100 Watts. Hot GaAsfet downconverter varicap tunes whole 420-450 MHz band to your TV ch3. 7.5x7.5x2.7" aluminum box.

Transmitters sold only to licensed amateurs, for legal purposes, verified in the latest Callbook or send copy of new license. Call or write now for our complete ATV catalog including downconverters, transmitters, linear amps, and antennas for the 400, 900 & 1200 MHz bands.

Microwave Construction Practices

Let's continue where we left off last month when we covered the construction of a basic SSB system. This month I would like to continue with the construction of some basic elements. I will be going into detail on construction techniques for successful projects, describing some useful tools. A lot of questions need to be answered for those just starting a project—but not all can be anticipated. However, with luck, this column should put some of the construction detail questions to rest.

Let's start by discussing some tools and equipment necessary for modifying (or performing brain surgery on) some of our microwave circuitry. Most of these tools must be small or miniature due to the compactness of most microwave circuitry. A basic bench setup consists of diagonal pliers, long-nosed pliers, and various screwdrivers. The soldering iron should actually be a good soldering station. By that I mean a temperature-controlled soldering iron. That's one key pointer for good construction: a low-voltage soldering station.

It pays to search out the nearest "beauty junk box," which is usually found close to the bathroom mirror. What we're searching for are a couple of small pairs of tweezers. I procured mine from the local drugstore in the cosmetics section. The ones from Revlon are the best, but they carry a good price tag. I selected one that had a large, stout hand-hold section and then formed down into a small narrow end section, with a total length of about six inches. They worked out well for selecting components and positioning them on PC boards.

An alternate method is to just dump the component onto the PC board, then try to position it into place with a toothpick, using shuffle-board action. It's not the best but it will work in a pinch. I prefer the tweezers. Part of my trick in using them with very small components lies in the PC board preparation. Here I am talking chip resistors and capacitors and other small surface-mounted parts. Next, I will cover semiconductors and the method used to place them on a PC board.

Positioning Small Components

The real question is: How do you successfully hold a squirming chip resistor or capacitor on a PC board when it's only 0.050" square? Their small size makes them hard to position in place for soldering. Well, that's

partly where the tweezers come into play, but the secret is PC board preparation. If the board is home-brewed like the ones you or I make, they need two preparation steps before soldering. This is not 100% necessary but it can make it easier to place chip components on PC boards. Besides, it doesn't hurt to make the

iron. The board is first lightly coated with liquid rosin. You can use a small paint brush similar to a watercolor brush to apply the rosin to the copper traces. However, I prefer to wet my finger with rosin and apply it with a rubbing action on the copper traces. A liberal amount will work OK, but a little dab will do just fine.

Once the rosin is applied, use a soldering iron with a small amount of solder and gently rub the solder onto the trace. You will notice that using rosin helps the solder to flow, so you don't need to use as much. As you move the soldering iron, add solder

the excess rosin on the board at this time as it is somewhat sticky and will hold a part once it's positioned on the board. If you want, recoat the trace: on top of the solder with a light coat of rosin to help hold chip components. You will probably have to try several of these methods out and find which ones you like best. It's an individual thing.

Chip components are soldered to the trace at one end of the chip. First wet the trace with solder in front of the part. Use a small amount of solder then with a toothpick in the other hand hold the part in place and draw the melted solder pool just in front of one edge of the part up to and over the top of the chip component. Use a sweeping motion over the top of the part. Inspection with a magnifying glass should show a good solder joint looking like a ramp up to the shoulder of the chip component (see Figure 2). If the part moved, re-solder and reposition it before soldering the other end of the component. Once one end of the component looks OK, solder the opposite end of the part to complete installation. Do the same for all components that you need to install, except the diodes and transistors (or FETs). Don't worry about the mess rosin at this time.

When you are ready to mount your diodes and FETs some special precautions are necessary. For most diodes this is not a problem; however, for some signal diodes and expensive Schottky types precautions don't hurt. The diodes and FETs should be handled with proper static precaution taking care not to destroy these parts before installing them in a circuit. There is no need to fret about static-sensitive components as the precautions for using them are not too demanding. Mounting them with grounded work station will remove the static voltage.

Removing the Rosin

When the other components are mounted it's time to remove the rosin which looks quite sloppy on the board. Removing rosin is important because it can have a detrimental effect on the board. It can de-tune the microwave stripline and cause excess loss. It can

Photo A. This unit has been modified countless times and the FET is still performing well. The circuit is a 10 GHz amp, modified into a 10 GHz mixer. The circuitry at the bottom is a bias supply.

project look a little nicer. The first step in board preparation is to apply a thin solder coat on the stripline traces to help in the component soldering operation. This step is performed before any components are mounted on the PC board. A solder-coated PC board is easy to solder and this step also helps to prevent oxidation of the copper surface.

The solder coat operation can be performed with any small soldering

only when necessary to fully coat the trace. In this way the PC board will become fully coated with a very thin layer of solder on the traces and ground surfaces. This will give your PC board resistance to oxidation and help in the soldering of chip components.

I can't stress this enough: Use solder sparingly. A very small amount can be spread across the trace with the aid of some excess rosin. Leave

also attract the most undesirable material and stick to it, further de-tuning your circuit.

The best method to remove this grungy (rosin) is to use a small plumber's acid brush dipped in alcohol. These brushes are available in most hardware stores for about 20 cents each. Wash the PC board with it. Dip the brush in rubbing alcohol and apply it to the PC board on a slight slope to allow the liquid to run off the bottom of the board. Continue to apply with a rubbing motion with the brush, dipped in alcohol frequently, until all the rosin is removed.

For small PC boards, hold the

board above a glass ashtray, using it for a container for the alcohol. Use a small amount of alcohol; a capful or two is sufficient. Alcohol is flammable so keep it away from heat sources. You might need a second rinse to give the board a very clean appearance. Once the board is clean, air dry it or wipe it dry with a rag before mounting the semiconductors and FETs. Always use the grounded static-free work station for this operation.

Other Tools

Now, here are some of other tools to get, besides the tweezers: magnifying glass or eyepiece, some tooth-

picks, liquid rosin, plumbers' small acid brushes, small diagonal cutters, plus long-nosed or needle-nosed pliers and a good temperature-controlled soldering station. Add to these items a good selection of X-acto handles and blades that will be used in the tuning and cutting of PC board traces to make modifications to the stripline circuitry. These modifications are very necessary to microwave circuitry, and are done with X-acto knives. In this phase of modification you will be cutting traces and trimming them with the knife blades. In microwave work these are our variable inductors and capacitors that are

formed by traces on the PC board. When you make cuts, hold the knife firmly and do not push hard on the Teflon PC board—Teflon microwave substrate is very soft and light pressure is all that is necessary. Be sure the DC power is off when doing any trimming on PC boards.

Toothpicks are used to make tuning tools. Glue small bits of copper on the ends of several toothpicks and when they're dry they can be moved about active amplifiers to give you an idea of where to solder permanent copper straps to the stripline. These toothpick tools are quite simple—just don't touch two adjacent leads together because a short is a short is a short, and will most likely smoke a component.

The Static-Free Work Station

At this point, let's describe the static-free work station where we will assemble and mount the static-sensitive components. This can sound quite impressive, but actually it is very simple and easy to construct. The main difference is that all construction is done on a sheet of scrap metal or circuit PC board used for a common ground surface, to which all components and tools are grounded. This removes any static buildup from your work area. No dragging your feet on a carpet before going to work at the station! Sparks are not permitted. If you

fear the worst, do your construction on a moist day, a minimum static day. Still use the grounded work location.

Your work station pad (a sheet of copper or conductive metal) is where we place the circuit to be worked on (the PC board). Adjacent to the area reside the temperature-controlled soldering iron, tools, and you! Be sure to use a resistive conductive wrist strap and not a direct connection to your wrist. Usually these wrist straps have a built-in resistor in the clip lead portion with a resistance of a half megohm or so for a safety factor. The high resistance is so that current that can be dangerous to you will not flow. It will remove static and bleed it off to ground; discharge it. The purpose is to remove static and not carry enough current to light you up.

Don't fall into the trap of "cheating" by touching and holding the grounded work station with your finger while trying to perform the operation. This is not recommended—it is asking for trouble. Use the wrist strap and its protective series resistance. It is there for your protection.

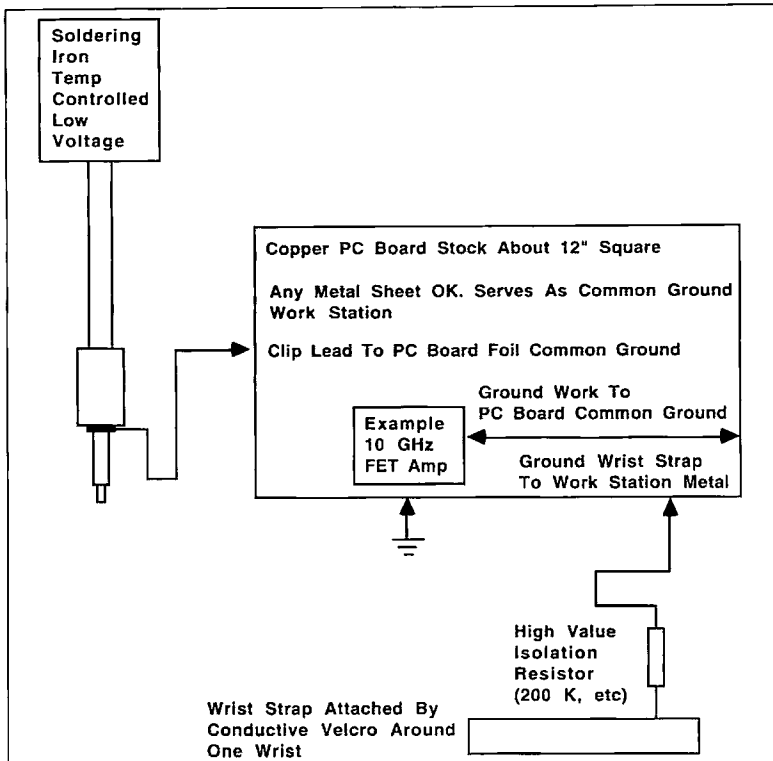

Figure 4. Construction of grounded work station. Notice that the soldering iron, work piece, and your wrist are all common grounded to prevent static from destroying sensitive FETs.

Soldering Iron Grounds

The only major tool purchase should be a temperature-controlled soldering station. Most used ones or even many new ones do not have a ground connection brought out to a clip lead. They are grounded in some cases; always check. If you do not have a ground clip lead it can be added to the low voltage portion of the iron. These irons are operated from 110 AC and converted to a low voltage in the base unit. Usually it converts to around 24 volts to heat the iron element. To add a ground connection to this type of iron, make a connection from the barrel of the iron at a low temperature point, or better still through the iron's ground lead to the transformer's base. In this case, a connection can be made in the transformer base unit and brought out for connection to the work station.

This clip lead connection is used to remove static from the metal portion of the low voltage iron so as not to harm the semiconductor when you solder it. If you have a high-voltage iron, one that works and heats from

110 VAC directly, this can be made to work as well. What you have to do is *unplug* the iron just before each soldering operation (with the same type ground clip). Prior to attaching a ground clip on this type of iron verify its AC leakage voltage, a safety factor.

We are doing this to see if the tip is insulated from the heating unit, which is a 110 VAC element. Sometimes the insulation breaks down and allows AC to flow through this defect. It's a safety item and should be checked every so often. Be careful and use insulated test leads for the AC voltage check. I have checked similar irons and good ones will show very low voltage readings, less than a volt or so. However, I have found some that were almost direct connections to 110 VAC due to cracked insulation in older irons. Check to be sure for safety and semiconductor survival.

Mounting Semiconductors

Mounting the semiconductors is very easy. I mount the diodes first. On every small glass-leaded diodes be careful not to bend the leads too close to the package for soldering as the glass can crack on this type of diode during mounting. Just bend the leads to the position you want them and allow a little slack in the leads about 1/8 inch. Use the tweezers to serve as a heat sink and grounded installa-

tion tool when soldering. Prior to mounting FETs, all PC board preparation such as cutting mounting holes or source ground "C" straps should be complete.

Follow the FET mounting instructions. If they state to mount the FET upside-down you need to cut (with the X-acto knife) a 0.1"-square hole to position the FET into. In this case, the

source inductance are requirements, particularly at 10 GHz. In 10 GHz amplifiers that we have constructed, the minimum inductance or shortest lead length was found to be the best solution to achieving maximum gain and uniform operation at 10 GHz. Both using the "C" straps and mounting over metal devices upside-down can achieve the same results: stage gain

the FET or the FET and "C" straps. "C" straps are made from thin copper flashing material and are about 0.050" wide. As shown in Figure 3, they are soldered onto both sides of the PC board. One side is the rear ground foil and the other side is the stripline side source trace for grounding. These straps resemble a "C" when they are formed through a PC board hole.

The last thing to remember is mounting the FETs. They are stored in a static-sensitive protection package and should be picked up only with grounded tweezers. Touch the envelope or box conductive portion (FET storage shipment container) with the grounded tweezers first before touching the FET. This will discharge any differences between the ground surfaces of the work station and the package or envelope. Then, and only then, pick up the FET and place it directly where the device is to be soldered onto the PC board. Once soldered on the PC board the FET is protected by circuit terminations on the board.

Well, that's it for this month. Hope you enjoyed this month's shop talk. As you can see, an elaborate workbench is not required. Happy construction! As always I will be glad to answer questions concerning this and other topics. Please send an SASE for a prompt reply. 73 Chuck WB6IGP.

73

"Check the details on construction for the project you plan to duplicate. Use their recommendations."

ground side of the PC board is soldered to the gold of the FET for minimum source inductance (see Figure 1). If the FET is mounted right-side-up, most likely "C" straps are being used and the circuit allowances were made for some slight inductance. In some cases I have even seen right-mounted FETs; that is, the opposite lead has been trimmed off and the remaining source lead is connected to ground with an additional short section of solid wire. This is a stabilizing technique (degeneration) and is used at frequencies lower than 3 GHz.

The "C" straps and minimum

and minimum inductance. Check the details on construction for the project you plan to duplicate. Use their recommendations.

In case of trouble, it helps to have the side of the hole beefed up with a small scrap of copper foil to aid in soldering to the top of the upside-down FET. The thing to be careful about is that the "C" straps do not short out the GATE or DRAIN leads to ground. If this dimension looks close, trim with an X-acto knife for some clearance between leads before mounting the FET. In either case, the hole cut into the PC board will accommodate either

- Packet Radio - Portable & Affordable!

Model BP-1
Packet Modem
Made in U.S.A.

- ★ Simple Installation
- ★ No External Power
- ★ Smart Dog™ Timer
- ★ Perfect For Portable
- ★ Assembled & Tested
- ★ VHF, UHF, HF (10M)

Whether you're an experienced packeteer or a newcomer wanting to explore packet for the first time, this is what you've been waiting for! Thanks to a breakthrough in digital signal processing, we have developed a tiny, full-featured, packet modem at an unprecedented low price. The BayPac Model BP-1 transforms your PC-compatible computer into a powerful Packet TNC, capable of supporting sophisticated features like digipeating, file transfers, and remote terminal access. NOW is the time for YOU to join the **PACKET REVOLUTION!**

CIRCLE 269 ON READER SERVICE CARD

INTRODUCING THE UNIVERSAL M-400 A totally new concept in code / tone readers!

- A RTTY-reader and tone-decoder in one!
- Easy to read two-line 40 character LCD.
- No computer or monitor required.

- Baudot
- Sitor A/B
- ASCII
- Swed-ARQ
- FEC-A
- FAX
- POCSAG
- GOLAY
- ACARS
- DTMF
- CTCSS (PL)
- DCS (DPL)

Forget the limitations you have come to expect from most "readers". The self-contained Universal M-400 is a sophisticated decoder and tone reader offering an exceptional range of capabilities. The SWL will be able to decode Baudot, SITOR A & B, FEC-A, ASCII and SWED-ARQ. Weather FAX can also be decoded to the printer port. The VHF-UHF listener will be able to copy the ACARS VHF aviation teletype mode plus GOLAY and POCSAG digital pager modes. Off-the-air decoding of DTMF, CTCSS (PL) and DCS is also supported. The M-400 can even be programmed to pass only the audio you want to hear based on CTCSS, DCS or DTMF codes of your choosing. The M-400 can run from 12 VDC or with the supplied wall adapter. The American-made Universal M-400 is the affordable accessory for every shortwave or scanner enthusiast.

Only \$399.95 (+\$6 UPS).

Let's Mobile

Last month, we were talking about mobile operation. Before we continue, I'd like to pass along a fix for a problem I ran into.

A Detective Story

At a recent hamfest, I picked up a used Kenwood MC-85 desk microphone. It's a nifty microphone which has a condenser mike, built-in compressor and outputs for three separate rigs. I mentioned my purchase to a good friend who used to own one, and he warned me that the mike was very sensitive to RF feedback and, thus, poor for HF. I figured his must have had some kind of problem and proceeded to wire the cable up for my Yaesu FT-747GX.

I keyed up and it worked great! I got several good reports and apparently had no RF feedback problems. I was happy. The next night, I had a sked with my friend, and he reported that I sounded *terrible*, with lots of RF feedback. A quick listen on another receiver confirmed his report: The thing was a disaster. What had happened in the preceding 24 hours?

Ah, Sweet Ground

Usually, when you have an RF feedback problem you have a lousy ground connection somewhere. Finding it isn't always easy, though. In fact, I've had some tough times with these kinds of problems. But not this time. The thing gave itself away when I noticed that grabbing the mike's metal gooseneck, which also encloses the mike element itself, caused extra RF feedback pops and noises. Yet, touching the rest of the metal housing did not have any effect. Now I knew: The gooseneck was not properly grounded to the housing. Upon opening the unit, I discovered that it is built in two pieces. The PC board is mounted and grounded to a metal frame which then screws to the housing. The gooseneck is screwed directly to the housing. So, if the screws holding the frame to the housing are even a little bit loose, the ground between the gooseneck and the PC board gets funny. The cure was easy: I added a ground wire directly from the gooseneck's nut to the PC board's frame. Voilà, no more RF feedback! If you have an MC-85, you might want to add this wire, especially if you have had any feedback problems.

Back To The Car

Out of the shack and back into the car. OK, you've installed your HF rig; you've run your fused, heavy-duty

power cable from the battery to the radio; and you've installed and wired your antenna. You turn it on and, hey, it works! Sounds nice and clear, too. But wait, you haven't turned the engine on. Uh oh, now it sounds like garbage. Noise and static out the wazoo. Unfortunately, when you are running a multi-kilovolt ignition system a few feet from a device designed to detect a fraction of a microvolt of RF, you're gonna have some problems. Is it possible to get decent reception in the car?

You Betcha

It'll never be as noise-free as a good, quiet home station, but you can get good results in the car. As an example, my Mazda RX-7 used to have an S-7 to S-9 static level, even with the rig's noise blanker on. (It should always be on.) I just assumed that was the best I could do and was resigned to living with it. Consequently, I rarely operated HF in the car. A few months ago, the car started running poorly, so I decided to give it a tuneup. I changed the plugs, wires, rotor and distributor cap. Hey, my noise level went down to S-3! And my car ran great, too. Ignition problems, and especially bad plug wires, can really drive the noise level up.

Other Sources

There are lots of other noise sources in an automobile. Any poorly joined body parts can make electrical noise as they rub with the car's motion. Even wheel bearings can make noise! There are too many potential problems and solutions to cover here, so, if you have a really stubborn static problem, get a book devoted to mobile radio installation.

There are two big noise sources which keep cropping up: fuel injectors and the car's computer. Some makes and models have particular problems which are known to the manufacturers, and a call to the dealer may bring forth an internal memo on the subject. Then again, it may not. Some injectors and computers are just noisy and there's nothing you can do about it. Sometimes, though, the manufacturers have replacement parts or modifications which greatly reduce the noise. Some will even do it for free.

Warning!

As you can see, it is very common for your radio to be QRM'd by your car. But there's something worse: You can QRM your car! Today's cars are electronically sophisticated; virtually all use computers to control the engine. Some also use them to generate the dashboard displays, control the cabin environment and various other things. Some of these computers are quite sensitive to RF, and a few can actually be destroyed by your transmitter, even

if it is only a 25 watt VHF rig! If your car misfires or otherwise misbehaves when you key up, you are probably trashing the computer, so you should investigate the problem before you cause some expensive damage.

Honest, Officer, I Didn't Mean It

I remember using my 100 watt HF rig in my old car, which was a 1984 Oldsmobile Cutlass. Once, while tooling around in the Vermont mountains, I was yakking away while rolling along under cruise control. Normally, I watch the speedometer carefully, even when I use the "autopilot." This time, though, I got distracted and never looked down. Suddenly, it seemed like I was going awfully fast. Sure enough, I was doing 85 and still accelerating at the maximum rate. Yikes! I reset the cruise control and everything was fine. And I never got it to do that again. But I have no doubt that my transmitter caused it. Thank goodness I didn't get caught; I would have never explained that one.

There have been many reports circulating on packet radio regarding Toyota Camry computers being destroyed by RF. In fact, several hams wound up with repair bills over \$1,000, because the damage wasn't covered under warranty. Apparently, there was an internal memo stating that radios over 10 watts output shouldn't be installed in those vehicles. Last I heard, though, the problem had been fixed. This is only a rumor, however. If you are contemplating getting one of these cars, you might want to check with your dealer before you buy. If you already have one, it would pay to find out if you're courting disaster every time you check into the local repeater.

The Skyhook

Mobile antennas present extra challenges at HF, mostly because of their small size relative to frequency. The standard mid-position loading coil arrangement works fairly well above the 40 meter band, but I haven't had much luck with it on 40 and 75; the efficiency is just too low. But there are other designs which work reasonably well, although nothing is going to work as well as a dipole 50 feet up! The oddest automotive HF antenna I ever saw belonged to a guy I met at a New England hamfest. It's kind of hard to describe this thing: The best I can say is it was horizontal, took up the entire length of his large, American car, and made his vehicle look like something from another planet. He designed it himself, and he claimed it worked like gangbusters on 75 meters.

Although there are several antenna tuners made for HF mobiling, I think it pays to get your antenna as resonant as you can. Efficiency is not that high to begin with, so you're better off if you don't have to use a tuner.

Sometimes, it seems like you have better bandwidth and lower SWR than you expect to get. Before you go rejoicing, take a look at your ground connection between the antenna mount and the car. Usually, a too-good

SWR over too wide a bandwidth means you have exceptionally poor efficiency and are losing a lot to resistive loss. Remember, a dummy load a ways has the best SWR.

Louder?

Can you install a linear amp in your car? You sure can! There are seven which have been made over the years and at least one is still available. Needless to say, you're gonna need some serious amperage to run something like that. A big battery and a giant alternator will need to be routed through humongous cables to the amp. And don't forget that all that RF power will be 2 or 3 feet from your head. Personally, I think I'll pass.

Pounding Brass

Can you pound brass in your car? Sure! I've tried it a few times, using the Microkeyer iambic keyer project I published some time ago. It works and it's fun, but you need to be a decent C'op to avoid getting so distracted that you impair your driving. Obviously, you can't be writing anything down while you drive, so you need to copy in your head. RF feedback into the keyer's hand key can be a problem which results in RF burns on your fingers. Be sure to use shielded cable from the key or keyer to the rig.

Well, that about covers it for mobile operation. There's a special thrill you get from talking around the world, around town, while you cover the distance between home and work, wherever. Happy and safe mobiling! Now, let's look at a letter:

Dear Kaboom,

I'm considering upgrading my station and I'm very interested in DS (digital signal processing). Several rigs offer inboard IF-level DSP units and there also are several third-party outboard AF-level DSP units available. Which is better?

Signe
Dr. Di

Dear Dr.,

In theory, IF-level signal processing should always be better than AF-level processing, because you deal with a signal before the AGC stages. That way, if you remove an offending signal it won't cause unwanted AGC action. With AF-level processing, you have control over that, and strong interfering signals near the one you want to copy can still cause trouble, even though I filter has taken them out, because it causes the AGC to clamp down.

As practiced today, though, it's a different story. The functions available in the inboard units just don't compare the neat stuff you can buy in the outboard, AF-level boxes. So, for now, I recommend you go with the outboard approach. Perhaps in a few years rig makers will put some serious effort into DSP and catch up with the specialty makers. By the way, I cover this subject in some detail in the July and August 1993 issues of *Radio F*. You might want to check those out. Enjoy your new gear! 73 and see you all next month, de KB1UM.

HAM HELP

mamin Tan, United Marketing, Isabela, Basilan Province, 7300 Philippines.

I am looking for mods for the HTX-202 2m HT. If anyone has any, please send to Trevor Davis VE3DKV, 107 Government Road East, Kirkland Lake, Ontario, Canada P2N 1A9.

I am looking for the schematics, manual, or info on the Hammarlund FM50a or its power supply. I will gladly pay for copies and shipping. I am trying to use this unit for Civil Air Patrol communications. Any information will be helpful. Thank you. KB2QGO, (716) 526-5336.

Sell your product in 73 Amateur Radio Today! Call Dan Harper at 800-274-7373.

We are happy to provide Ham Help listings free on a space available basis. To make our job easier and to ensure that your listing is correct, please type or print your request clearly, double spaced, on a full (8 1/2" x 11") sheet of paper. You may also upload a listing as E-mail to Sysop to the 73 BBS /Special Events Message Area #11. (2400 baud, 8 data bits, no parity, 1 stop bit. (603) 924-9343). Please indicate if it is for publication. Use upper- and lower-case letters where appropriate. Also, print numbers carefully—a 1, for example, can be misread as the letters l or i, or even the number 7. Specifically mention that your message is for the Ham Help Column. Please remember to acknowledge responses to your requests. Thank you for your cooperation.

I need operation and service manuals for COLLINS Model 32MS-1C tube-type transceiver, Serial #287. I will pay copying and mailing expenses; or furnish me the latest mailing address of Collins Radio, Canada or USA. Thanks to all who respond. Ben-

Low-Angle Radiation and a Gigahertz of Coverage on VHF/UHF! The FLYTECRAFT™ Model CFN

Listen for them on the air!

- The Model CFN is the ultimate compact, rugged antenna for 50 to 1.3 Ghz use. (Transmit from 144 to 1.3 Ghz) • Average SWR - 1.5 across transmit range. • Amateur radio licensees operate all bands - 2M, 220, 450, 900, and 1.2 Ghz • Novices! Ideal for operation in 220 or 1.2 Ghz band for which you have privileges. • Low vertical angle radiation • Large capture area • Rated 200W • Use indoors or out: CFN is lightweight, but tough - withstands hurricane-force winds. • Instant assembly - ideal for permanent, portable, or Field Day! • Attractive, strong design. Unique, futuristic appearance. 23.25" high.

Built with pride & sold worldwide - FLYTECRAFT™ USA

MULTIPLE CONTROL HEADS! HF SSB TRANSCEIVER

Most hams would never subject our SG-2000 all frequency HF transceiver to the kind of extreme conditions we designed it for. You'd likely be satisfied having 150 watt output, 644 ITU channels, 100 user defined (bam) frequencies in memory plus a direct entry VFO with 10 Hz stability, full frequency coverage, CW with sidetone and a superb 2:1 IF shape factor. Features such as FCC Type Approval, made with pride in America, direct Weatherfax support, up to 8 control heads and full performance from -22F to +140F might seem a bit extreme and for under \$2000. But if you've ever chewed the rag on 20 meters in a Force 9 Artic gale, you'll appreciate that there's a difference between extreme performance and performance in the extremes.

EXTREME PERFORMANCE

SGC Building, 13737 S.E. 26th St. PO box 3526 Bellevue, WA 98007 Tel: 206-328834 Fax: 206-746-6384 Tel: (206) 746-6384

NEVER SAY DIE

Continued from page 4

The main problem is that we're not interesting our newcomers enough to hold them. They go to a club meeting or two, find they are treated like lepers, and give up. Ten meters is nearly dead and will be for a few years. And CW at 5 wpm isn't nearly as much fun as you've told them it is. The result is that 94% of the Novices aren't seriously active. They spend less than an hour a week. That rattle you hear is amateur radio's death rattle unless you can figure some way to make hamming more fun. Fast. We're dying.

Oh well, Novices are kids anyway, right? Well, not exactly. Their average age is 39. Heck, when I got started in amateur radio the average age for all hams was about 32. Now the Techs average 45 and it's 50 for all hams, which puts the Advanced and Extras up in the 60s. No wonder almost everyone I work on 20m is retired.

Has your club made any effort to get newcomers to your meetings and get them involved with club activities? The answer, with very few exceptions, is no. Two-thirds of the Novices have never been to a club meeting. Most of the rest tried one or two and gave up in disgust. Very few said they were involved with any club activities.

What ever happened to the old ham radio fraternity concept? I read many of the club newsletters and I see

very little evidence of efforts to involve newcomers. We've let the hobby turn sour on our watch. We're putting up with bad language on our bands. Our personal ethics are a mess. We've cut off our newcomers. We used to be very proud of being hams. And rightly. We were the pioneers of all new radio modes. We were the major supplier of the best engineers and technicians to industry. And when WWII came along we helped save the country's bacon by volunteering for military duty. Eighty percent of us joined the armed forces. And don't you forget that it was electronics that was our big edge. It was a technology war and we hams were right there in the thick of it.

We've let ourselves become virtually useless. In 1964 we killed off thousands of school radio clubs. These were the clubs that led us young newcomers and we've never had any significant growth since. Nor, lacking the enthusiasm and drive of youngsters, have we been able to keep up with commercial technology, much less be in the forefront.

If you were running a business and you found that you were getting fewer and fewer customers, would you consider making some changes? Worse, most of the new customers you get to come in the door go right back out and don't come back. Are you doing something wrong? Has your product or service kept up with the world as it is today?

In business you either grow or die. So what's holding back our growth? I've been talking about that in my editorials, so my ideas on the subject won't be any news flash for you. But let's not just accept my ideas. And let's not stick by the ARRL's either. Let's survey the kids and find out why they're not interested in amateur radio any more. Yes, I know all the old excuses. TV, video games, on-line computer services and such keep kids too busy for them to take the time to learn the code and memorize the pathetically simple tests we've got set up as obstacles to keep out the "wrong" people.

Well, I've seen no sign that we've had any success in barring the wrong people. We've done a really fabulous job of keeping a lot of "right" people out.

The League hasn't a clue as to what to do to turn things around. They're asking, "What, if anything, can be done to reverse the trend?" Am I exaggerating? Check out page 9, July 1993, QST, last paragraph.

Wayne's Prescription

I'd like to see amateur radio fulfill its real potential . . . to help kids, our country and the world. I'd like to see millions of kids getting on the air and filling up our incredibly valuable, but presently vacant, microwave and satellite bands. I'd like to see 'em experimenting, building kits, and pio-

neering new technologies. We have no shortage of new modes for them to develop.

One thing we do know from experience is that everything our government does it messes up, and the management of amateur radio is no exception. I wish the socialists and liberals left would go live awhile in the remaining socialist countries, China and Cuba, and get over their delusions. Maybe they'd stop trying to get the government to do everything for us.

My dream is to have amateur radio run by our radio clubs instead of the government. The clubs would be responsible for recruiting newcomers . . . kids in particular. They'd Elmer radio clubs in schools. The clubs would teach theory and operating practice; and then would license the member who earns the privilege. The club would be responsible for their licensees and for the de-licensing of any member abusing our privileges.

I envision a national conference every other year where delegates from each of the clubs would discuss any vote on any rule changes proposed by the clubs. I'm sure you can come up with a long list of reasons why this wouldn't work. But I warn you, though I haven't taken 10 pages here to try and refute your objections, I doubt the you'll be able to come up with one for which I haven't a good answer. I've given this a lot of thought.

Indeed, a few years ago I made the

AUTOMATIC SIMPLEX REPEATER

THE SR-7110 CONNECTS TO ANY TRANSCEIVER TO MAKE A SIMPLEX REPEATER

- Portable or mobile repeater to increase the range of HTs • Emergency repeater • Test repeater to hear your own signal • Test for skip conditions • Unmanned hidden transmitter • Calling frequency machine

The 7110 has two modes of operation. In the automatic mode the repeater only repeats when there is no reply to a transmission within two seconds. In the continuous mode all transmissions are repeated without delay. The 7110PL has a PL decoder so the frequency can be used without the repeater.
SR-7110 \$200.00 SR-7110PL \$275.00

rounds of the FCC Commissioners and asked them how they liked the idea. The all agreed it would be a great system. They also agreed that the FCC would be glad to provide whatever legal expertise might be needed in the framing of new rules. The FCC would love to get out from under the expense and aggravation of handling our rule making and licensing. The Commissioners know little about amateur radio and, for the most part, would prefer to keep it that way. Well, if the White House ever gets around to appointing some new Commissioners we'll have a fresh opportunity to rewrite our ticket.

I've pointed out in my recent editorials that unless we do come up with some major changes in our hobby, we're sitting ducks for any well-funded obnoxious effort to knock off. Our bands are essentially up for grabs unless we re-invent a relevant need for them. I recommend this be centered around our 21st century need for one hell of a sharp bunch of engineers, technicians and scientists. Without 'em our American standard of living is going to keep in dropping, and so will the dollar.

Technology developments in communications, computers and transportation have narrowed the oceans which isolated us from Europe and Asia. We're now in competition with the whole world and we'd better understand this and stop trying to erect trade barriers to protect our under-

skilled, undereducated workers.

The most successful countries are going to be those making high-tech products. The big money is in manufacturing, not flipping hamburgers or sorting mail by hand. So we've got to re-invent our whole lousy school system so we can create a flood of youngsters who are excited about technology and looking for high-tech careers. Super Mario Brothers isn't going to do it. Even CompuServe isn't going to do it. The only hobby we have with the potential to fire the enthusiasm of millions of kids to learn about electronics is amateur radio.

We can get 'em on the air. We can set up our ham satellites so they can talk anywhere in the world 24 hours a day. We can get 'em excited about fox hunting, QRP, packet, SSTV, and so on. Maybe we can get back to where we were in the 1950s when 80% of all newcomers to amateur radio were youngsters, and where 80% of them went on to high-tech careers as a result. If America doesn't manufacture the electronic equipment for our businesses and homes, you can be sure someone else will, and where these factories go, so will the biggest banks, and the highest quality of life.

Can the FBI Help?

Voice-operated transmit (VOX) seemed like a great idea when it was invented, but it never got off the ground. You know why? Several rea-

sons. The clanking of the antenna relay was one big problem. The slow recovery time of most receivers was another. But the worst was that if there was any interference the other station was never sure just when you were listening. So what happened when ops used their VOX was they'd keep right on talking to keep that relay from clacking. In between sentences they'd "aaaaah" it to hold the rig on the air.

Modern technology has done away with most of the relay noise and has improved our receiver's ability to be turned on and off quickly. That leaves us with only one minor problem: letting the other person know when we've stopped transmitting.

The best way to generate normal conversations instead of our one-way broadcasts to each other is to separate our transmitters and receivers by a few miles so we can listen while we're talking . . . as I suggested recently. But if this is beyond your ability to handle, the next best approach is fast break-in (FBI). Now, in order to let the other person know when you've stopped transmitting I suggest you add a little beep, like the ones we use on our repeaters.

Let's see what you can do about building a circuit which will automatically beep or chirp when you stand by. If this catches on we'll soon see it being built into the new rigs. In the meanwhile, look for some kits. Yes, I know, there are a few DX chaps al-

ready using this approach. Good. What I want is to help make it so we can have the most natural conversations possible. This will make hamming more fun and help attract more newcomers to the hobby. I've gotten several letters recently from non-hams saying they lost interest in getting a license after hearing how boring so many of our contacts are. I know I'd be a lot more active if more contacts were interesting.

Get busy and design a circuit, check it out, and send me an article so we can get a few hundred hams to build it.

Once we're using fast break-in we'll have to break the ID habit. Every 10 minutes is fine. And it isn't necessary to repeat my call all the time. I already know it just fine.

I'm hoping that between duplex and fast break-in we'll be able to start talking more naturally and as a result our contacts will start being more interesting. I'd still like to see some way to have you send a list of things you're interested in so I'd know what to ask you. I'll bet you've done some fascinating things I'd like to hear about. Maybe you've been some places I'd like to visit. Maybe we have some other hobbies in common. We could have a great time and really be looking for each other for more contacts.

But a stereotyped QSO bores me silly. I guess it wasn't so bad for the first 25 years or so, but it's gotten old.

For Repeaters only.

Receiver Voter 4 channel, signal-to-noise

Improve coverage by adding receivers.

- Expandable to 32 channels by adding additional cards
- Continuous voting
- Available as a card or in a rack system
- Can be used with RF links or Telco lines
- Select/disable switches available for manual override
- External disable inputs
- LED indicators of COR and voted signals
- Remote voted indicators pinned out
- Thousands in service
- Starting at \$370

Remote Base Interface

Add a Kenwood frequency agile remote base, now to 9 different repeater controllers.

- Connects and controls a maximum of 4 radios or bands
- Supports 16 Kenwood models
- Connects thru the radio's mike jack
- Controls frequency, power, RF power, CTCSS, Shift, etc.
- Expands user function output
- Just plug, program, and play
- \$275

A Quote from Forbes

A recent *Forbes* column by Peter Huber discussed the effect technology is having on us. For instance, when I was young we spent a lot of time on penmanship. Well, handwriting was how one communicated then. Typewriters were too expensive for the home and typing wasn't taught in school. Once typewriters were cheaper, the need for good penmanship disappeared.

Spelling was a big deal when I went to school. Now it's handled by my word processor, which catches my errors. Peter suggested that before long making kids memorize all the irregular spelling rules will be like making radio engineers learn the Morse code. Heh.

We'll soon have automatic language translation, and computers with voice input. Look where we are with bar-code and checkout counters which add up the items, calculate the change, debit the store inventory, and presumably even add in a few cents here and there to pad your bill. Fast-food cash registers have pictures instead of numbers, which is handy since fewer and fewer kids are being taught how to make change.

If you're into video you can have a complete video production lab at home and do what used to take millions of dollars in equipment all by yourself. In audio, DAT recorders are

under \$1,000 and outperform a whole studio full of gear from a few years ago. Gas stations let you pump your own and pay with a credit card, with no attendant needed. Well, we're a little behind on that one. I remember HB9RF doing that in Zurich over 20 years ago as we were driving to visit his moonbounce station.

"Are you keeping up with technology? As a ham you're expected by the public to be knowledgeable about high-tech."

Are you still writing by hand? You're two generations behind. I changed to typewriters as soon as I could, carrying portables with me on my trips. Then I changed to word processors, moving to a laptop system around 1980, as soon as the first one was available. I moved from CW to voice in 1939 . . . and from voice to RTTY in 1949. I put up my first repeater in 1969. Our pioneering HTs and repeaters of 1970 are now worldwide as cellular telephone systems.

And look what's happened to those microcomputer kits we were playing with in 1975! Now we're using them to replace million-dollar typesetting systems. One of the first ads for the MITS Altair 8800 computer appeared in 73.

Are you keeping up with technology?

As a ham you're expected by the public to be knowledgeable about high-tech. Can you see where technology is taking us? All you have to do to get ahead of the game is know something like that before others do. Joe Sugarman W9IQO figured out that there would be a market for electronic gadgets, so he started selling them by

mail as JS&A and made millions. Steve Jobs figured there was a market for a single-board microcomputer, and didn't do badly. Bill Gates figured these new micros would need operating systems and parlayed that idea into a few bil.

If you really want to feel bad you can dig out some old issues of 73 and read where I told anyone paying attention about these opportunities at the time, including the one Bill Gates exploited. There are just as many opportunities today, if you think in those terms. Steve Jobs started out with nothing but a prototype built by Steve Wozniak. Bill dropped out of Harvard to work for MITS, in Albuquerque, where the action was.

Communications, computers, information systems . . . all are changing.

We're ready for a major change in education which will generate a few more billionaires. Ditto health care, which is a trillion dollar industry, and growing fast. How close are you to the change? Close enough to see the opportunities and benefit?

Every major misery we have in America offers opportunities for the person willing to pioneer and work. The downside is that if you're money driven, your chances of making it big are not good. You'll do best if you see something that needs to be done, figure out how to do it, and then work hard. Bill Gates made his billions accidentally. He's still wrapped up in what he's doing, not in making money.

In my reports to the New Hampshire Economic Development Commission I've been coming up with endless ideas for new businesses and new areas that need to be researched and pioneered. My first reports have been reprinted in my *Declare War* book. Those since then are in my *Declare War Update* reports. They're available via Uncle Wayne's Book shelf.

One of my joys is in getting letter from hams thanking me for keeping a them through my editorials to get out there and be an entrepreneur. Some have been very successful, and a of them know a freedom they neve experienced before.

Notes from FN42

As this month's column is being written, we in the U.S.A. are watching Hurricane Emily churn toward the central East Coast, hoping the storm will not strengthen and cause damage to life and property. So far, we have been very lucky in that no loss of life has been suffered, even though the storm grazed the outer banks of North Carolina. Meanwhile, Typhoon Yancey was headed toward Okinawa and Japan, lashing out with high winds and heavy rain. I certainly hope that David Cowhig, Ambassador to Okinawa, and the rest of the people will be safe and secure.

I made it back to Colorado this summer, but wasn't able to have an eyeball with any of the Gunnison hams. I did find out that the tri-band beam received from Fran, the widow of Fred Palmbad W0CYM, was used during the Field Day operation, and that a plaque has been permanently placed on the beam by the Gunnison Valley ARC. Fran's generosity has certainly started me thinking about what amateur-related equipment I might leave to local hams or the local ham club to help further this fantastic hobby. I have already compiled a list and am planning to include it in the next update of my Last Will and Testament. I think that this is really a way that we can all get involved, but in a slightly different way. Think about it! Lastly, I am very happy to introduce a new Ambassador from the Philippines, Lorenzo D. Gaston DU1CHD/6. He sent along three submissions for our pleasure. Welcome, Lorenzo! That's all for this month. On to the great news from around the world! 73, Amie N1BAC.

Roundup

Dominican Republic Letter from Bill Meara N2CQR/HI8: Greetings from Santo Domingo, capital of the Dominican Republic ("The DR" for short), land of sunshine, merengue music, and FB ham radio! The members Radio Club Dominicano have authorized me to serve as '73 International's Dominican Republic Correspondent. I am on assignment with the U.S. Embassy here; my selection as correspondent was based largely on my more than 30 years of practice with the English language! We've seen the excellent reports from around the world and wanted to send in a contribution from the DR.

The Dominican Republic is located on the eastern two-thirds of the island of Hispaniola. We are on the large island between Cuba and Puerto Rico. The country has a population of over seven million and is Spanish-speak-

ing. French-speaking Haiti occupies the western third of the island.

Ham radio is big in the DR! A drive through Santo Domingo reveals numerous HF yagis. Radio Club Dominicano (HI8RCD) is the IARU affiliate and has been in operation since 1926. The club sports a complete HF station, along with 2 meter gear and packet equipment. A second club, Union Dominicano de Radio Aficionados, is also very active in Santo Domingo. In the country's second city (Santiago) there is much club activity, including the Hotel India DX Association.

Dominican hams are involved in a wide variety of radio operations. HF SSB DXing is the most popular. Geography has blessed the island with good DX conditions (we are surrounded by salt water and have abundant solar radiation!). There are approximately one million Dominicans living in the U.S. (mostly in the New York area), and amateurs among this expatriate population maintain schedules with ham friends on the home island. There is a lot of 2 meter FM activity, and the packet revolution has also swept through HI land. There is a small group of 6 meter enthusiasts providing a new country for VHF buffs. Hams here have worked the Mir space station, and there is interest in the satellite program.

The numbers after the HI prefix indicate geographic region (8 for the capital, 3 for Santiago, etc.). The suffix letters are usually based on the ham's initials. Old-timers are authorized single-letter suffixes. Foreigners operating with Dominican licenses have suffixes that begin with X. The DR has a reciprocal license agreement with the U.S.; hams operating under this agreement work with their home call, followed by /HI. ARRL headquarters has up-to-date information on the fairly simple process for obtaining reciprocal operating permission.

While not really in the category of rare DX, an HI call can stir up some pile-ups on the HF bands—lots of fun for a visiting U.S. ham.

Tourism is one of the country's largest industries, and we are sure that there are hams among the million or so sun-seekers who visit the DR's beautiful beaches every year. While most of the resort areas are quite distant from Santo Domingo, tourists do frequently make it to the capital. If you're coming to Santo Domingo, drop us a line, and we'll see if a visit to the club can be arranged.

Dominican hams are very friendly to hams from across the sea. HI8RCD currently has members from the U.S. and Japan. Over the years, foreigners on assignment in the DR have been very active in the local club.

We will try to provide '73 International' with periodic updates. For now, best of 73 from HI8!

[Bill Meara N2CQR/HI8, Unit 5510, APO AA 34041 USA]

Russia From Yuri V. Funkner, UN9LX (ex-UL7LS): The International Diploma Foundation is a nonprofit, volunteer effort devoted to the development of world amateur radio by means of establishment of various awards. Membership is open to anyone who shares the objectives of the foundation and is ready to pay the entrance fee. Donors will receive handsome certificates. All gifts will be acknowledged. For further information, write to: Yuri V. Funkner UN9LX, IDF Secretary, PO Box 1 Frunze 459411, Ordzhonikidzevskiy Rayon, Kustanayskaya Oblast, Republic of Kazakhstan. [Yuri also hosts a DX Net on 7043 KHz on Friday at 1900 UTC.]

Switzerland From the International Telecommunication Union (ITU) Press: The ITU has created a new strategic consultative body to step up telecommunications development worldwide. The Telecommunication Development Advisory Board (TDAB) held its first meeting on 6 and 7 July 1993 to advise ITU on priorities and strategies for telecommunication development, to advise ITU member countries on how best to step up telecommunications development and to reinforce the role of the development machinery of the Union in this area.

The board will neither exercise supervisory functions nor will it be involved in the management of ITU's development sector. It will, however, be required to:

- Provide views and recommendations that will contribute towards the development, expansion and efficient operation of telecommunications;
- Help in raising the level of awareness of decision-makers of the importance of telecommunications in socio-economic development of nations;
- Encourage the participation of industry, telecommunication operators and service providers, bilateral and multilateral organizations and financing institutions to promote telecommunications development in developing countries;
- Assist in the mobilization of actions and resources for pre-investment and investment activities in the field of telecommunications;
- Assist in the preparation of telecommunication development conferences.

U.S.A. From Patrick G. Lehrman N9JPV: The June issue of *Radio Fun* ran an article about the "School-to-School OSO Contest." Many schools, hams, and clubs in the U.S. and Canada have responded to that article. The contest started at 1200 UTC on October 5 and ran through 1200 UTC on October 6, 1993.

Please send photocopies of logs as well as any interesting stories to the Westmont Amateur Radio Club by December 31, 1993, at 125 S. Grant St., Westmont IL 60559-1907 U.S.A. [This letter described the contest but arrived too late to be included in the October issue before the contest.—Amie]

Well, the Amateur Radio Congress held in Las Palmas last fall, came great. We had hoped for more foreign participation, but about the only foreigners who showed up were the vice president of the French amateur radio organization and his wife, a Portuguese couple, and some Russians who sailed here in a Viking-type ship (I would be worth a story in itself) so months earlier. There was a wide array of activities, excursions, and such which they pulled off with the usual flair. This was another event in which a good time was had by all. More recently, it hosted a CW contest weekend. I'll have to get up that hill again to see what they're planning next.

In a previous report, I mentioned learning to make Canary knives so could know what I was talking about when I wrote about them. I suppose that is a worthy motive, but it certainly doesn't guarantee that if someone has experience, that they can then write clearly and correctly about a particular subject.

In a different report, I mentioned something about heroes in the mold of old. What I had in mind was heroism of moral courage instead of physical courage. People who can inspire us by the moral nobility they display under extraordinarily difficult circumstances. Isn't this what we need today? Certainly not more mercenaries, as noble as that is under certain circumstances. What I think of is people like Matthew Henson, who accompanied Peary in his achievements in the Arctic. We may be more than accompanied Peary referred to him as "indispensable, more of an Eskimo than some of them," and he is still greatly admired by the descendants of the Eskimos among whom he moved. "K Matthew" he was known among them, and my favorite photograph is of him holding a muskox calf in his arms (National Geographic Vol. 174 No. September 1988, p. 422).

He became one of the great hunters and sled drivers of all-time of living out his life as a shepherd's son he was. There is doubt that he had tremendous physical courage, but he also had more. Loyalty, humility—you might say reading his story.

MDLE

About 40 amateurs were present at Natanya's Goldar Hotel for the annual Israeli Packet Group's meeting.

opening address was given by pioneer packeleer Bentzi 4X1IL, while the Hannukah candles were lit by Yankel 4X1AH, IARC President. Further talks on subjects related to packet radio were made by Yossi 4X6KJ, IARC Chairman, Naftali 4Z4RM, and "Dima Danny" 4Z9DDA.

The Packet Cluster, which shall soon start operation on 144.675, the 4XNet frequency, was discussed by 4X1IL, 4X1GP, and 4X1DA. The first Cluster's callsign will be 4X4BX, in memorial to the late DXer Sioma Manzari 4X4BX, who was the first IARC chairman. Hot DX information will be transmitted to all Cluster members who have left their packet gear on the frequency in the same manner as in a telephone conference call.

Jim 4X1RU outlined the newest version, 5.14, of the F6FBB BBS program, which is installed in his BBS and requires one megabyte of computer memory. Mail from abroad comes through 4X1AS's satellite gateway and six European HF BBSs. Features of the new software are: a BBS data base which completes incomplete addresses automatically, a REJECT file to zap undesirables, and an SR (Send Reply) feature that automatically addresses according to the number of the message being answered. Jim also reviewed the amateur communications software being integrated into the Technion's satellite project, the Techsat.

Peleg 4X1GP clarified points on proper packet operation stressing the inclusion of one's own packet forwarding address in the body of the message, so that the addressee will know how to reply. Recommended operating parameters for the TNC dealing with switching time and delays for proper integration into the Net were discussed.

He also explained the TCP/IP protocol and the latest improvements made in it. He recalled the problem of the "hidden station" that reduces the through-put in the system to 18% of the capacity. He presented a solution where a commanding station will work as a digital regenerator transmitting what it's receiving simultaneously. This will raise the efficiency to 56% at the cost of allocating two frequencies to communication.

Shlomo 4X1AS described the communications programs (PG and PB) for working on the satellites OSCAR 16 (1200 baud) and OSCAR 22 (9600 baud). Messages are sent in the BROADCAST mode, and the satellite can be utilized by up to 20 users simultaneously. If 20 are already connected, you are given a number and must wait in line until your turn comes up. The satellite transmits 10 seconds to each connectee. Material stays in the satellite from two to four days and the local directory should be constantly updated. If the requested information is not received in the present pass, the program will automatically request it again when the bird comes overhead the next time. Files arrive in compressed form and as such are

transferred to 4X1RU, where they are unraveled. There are 25 satellite gateways in the world. Each one receives material only from other gateways and checks the satellite's directory if there are any messages for it.

All-in-all, this year's Packeteers' meeting was a fruitful one, giving a good forum for the exchange of ideas and furthering the advancement of the fast-growing field of digital communications in Israel. Looking back to the inception of packet in Israel a mere six years or so ago, the growth has been amazing. [Also amazing in the rest of the world too!—Amie]

OKINAWA JAPAN

David Cowhig 7J6CBQ/WA1LP
AmCon Naha
FBU PSC 556, Box 840
FPO AP 96372-0840

Now it is late June. The plum rain season has ended and we are moving into Okinawa's hot season. Soon will come the Eisa festivals throughout Okinawa (July and August) where the Okinawans, who follow the ancestor-veneration religion of the Chinese, welcome back the spirits of their ancestors for a three-day visit. Large groups of men and women dance in fine costumes, some carrying drums like those shown in JS6ANO Hokama-san's QSL card. The instruments and distinctive rhythms of Okinawan music, very different from those of the rest of Japan, owe much to Indonesia, Thailand, China and probably India as well.

When Emperor Akihito and Empress Michiko visited Okinawa in April they passed just 200 meters from our house in the central Okinawan village of Kitanakagusuku on their way to visit some handicapped children. Our neighbors waved Japanese flags as the couple drove by in their black limousine and helicopters circled overhead. Not to be left out, my children, Patrick and Frances KD4BMJ, grabbed Japanese flags and waved them enthusiastically as the Emperor and Empress passed by. I couldn't help but think what a wonderful difference 50 years makes!

One theme of the Emperor's visit for the National Arbor Day Celebration was reconciliation with the Okinawan people who had suffered terribly at the hands of the Japanese Imperial Army. Today, as they do every June 23, Okinawans remember the 200,000 Japanese, Americans, and Koreans who died here in 1945. The Okinawans plan to dedicate a memorial on the 50th anniversary of the Battle of Okinawa, which will have the names of all the soldiers—Japanese and American—who died in the battle. In the words of Jana, the 17th century Ryukyu Kingdom statesman, "inochi da takara"—"life is treasure."

During a mid-May trip to Yonaguni, the westernmost of the Japanese islands and home of the world's largest moth (wingspan up to 24 cm!), my efforts to reach Taiwan, just 80 miles, on 2 meters failed but I met island physi-

Photo A. QSL card of JS6ANO, showing dancers welcoming back the spirits of their ancestors.

cian Masaki Akamine JS6GNM, his wife Mimako JS6KHO and their two children. The Okinawa Prefectural government assigns Akamine-san to a new outlying island every two years. He likes islands so he started his assignment on Yonaguni, population 1800, in May 1993. I met JS6GNM on the 80-miles-distant 439.88 MHz JR6YI Ishigaki island repeater but soon switched to 2 meters simplex and then the eyeball mode since Akamine-san's home (and clinic) was just 50 meters from my minshuku (Japanese traditional-style hotel). The Akamines took me on a tour of the island while I worked in Honshu using his 3 watt Mizuno 21 MHz SSB handie talkie. We finished the evening in a restaurant run by Yonaguni Mayor Tsuimaji's family—named the White House, naruhodo (that's, of course, in Japanese).

Yonaguni lives by raising beef cattle, growing sugar cane and vegetables, fishing, selling the local awamori rice liquor (at 60% alcohol the strongest brew in all Japan), and tourism. Yonaguni enjoyed a brief boomtown era (the island population hit 12,000 in 1947) as Japan's Wild West just after World War II. Enterprising smugglers liberated goods from the US military PX for cheap Taiwan rice which they could sell for a 700% profit on the Japanese black market. [More next month!—Amie]

PHILIPPINES

Lorenzo D. Gaston DU1CHD/6
PO Box 27
6116 Silay City, Neg. Occ.
Philippines

Amateur Radio licenses in the Philippines are issued by the National Telecommunications Commission (NTC). NTC is under the Department of Transportation and Communications (DOTC). NTC is headed by one commissioner and assisted by three deputy commissioners. The NTC issues Amateur Radio Licenses and Radio Amateur Operator's Certificates with a maximum effectivity period of three years.

There are four classes of amateur radio licenses in the Philippines: Class

A, B, C, and D.

Class A licensees have full privileges and their authorized station power output is limited to 2 kW PEP SSB or 1 kW CW. Class A licensee who have operated for at least five years as Class A are qualified to be either appointed as club station Trustees or deputized by the NTC as Amateur Radio Inspectors or both. Class A licensees are assigned D-prefixes, but they are also given one option to change the callsign prefix from DU to either 4D, 4E, or 4F. A club station is required to have (qualified) Trustee. Licenses to operate repeaters are only granted to duly recognized amateur associations, clubs, or societies. All club stations and their repeater(s) have the same callsign and are assigned DX prefixes.

Class B licensees are not authorized to transmit on the 160 meter band. Operation on 20 meters is a lowed except on the segment from 14.100 to 14.275 MHz. Operation on all other bands and modes are a lowed and authorized station power output is limited to 1 kW PEP SSB or 500 watts CW. All Class B licensees are assigned DU prefixes.

Class C licensees are authorized transmit on all modes on 40, 15, 1 and 2 meters only. Authorized station power output is limited to 200 watt PEP SSB, 100 watts CW, and 1C watts on 2 meters. All Class C licensees are assigned DU prefixes.

Class D licensees are limited to meters only (all modes) and 100 watt power output. All Class D licensees are assigned DY prefixes (DY-prefix QSL cards are not valid for the UN-CD Award or any other award so please do not contact or send a QSL card a DY-prefix station on any band except 2 meters, just in case you hear one).

A "Radio Amateur Operator Certificate" is a certificate of authority issued by the NTC to a qualified person who has passed an appropriate amateur radio examination. This certificate authorizes the holder to operate any licensed amateur radio station of an appropriate class as indicated in the certificate.

Next month I will cover the reciprocal licensing in the Philippines. 73! E

OLTON, VT The Central Vermont ARC will operate the Vermont Girl Scout Council E Station W1BD from the Bolton Valley resort, 1700Z Nov. 6th-0200Z Nov. 7th. req.: 14.233, 7.233, 3.865 MHz. For a special Event QSL card, send QSL and ASE to CVARC/VGSC Special Event, c/o Box 674, Montpelier VT 05602-0674.

EW HAVEN, CT The South Central CT RA will operate W1GB 1400Z-2300Z to commemorate the operation of the first telephone switchboard in the U.S. Operation will be in the General 40 and 20 meter subbands. For a certificate, send QSL and 9" x 12" SASE to Bruce Torello AA1BX, 94 Dogwood Rd., Orange CT 06477.

NOV 6-11

UELPH, ONT., CANADA SE Station G3W will operate on 10, 15, 20, 40 and 80 meters as an "in memoriam" for the fall of both World Wars. Operation will be 11 AM-5 PM EST each day, with a minute silence at the 11th hour of the 11th day of the 11th month. For a QSL card, send IRC or Canadian Postage on SASE to G3W, c/o VE3ZM, P.O. Box 1305, Uelph, Ontario, Canada N1H 6N9.

NOV 11-12

LBUQUERQUE, NM The Albuquerque RC will operate WB5MI from 1700Z Nov. 11-1700Z Nov. 12th, to commemorate Veterans Day. The Station is located at the Veterans Administration Medical Bldg. For certificate, please send a QSL and a 9" x 12" SASE to AARC, P.O. Box 11853, Albuquerque NM 87192.

NOV 13-14

CHARLOTTE, NC Mecklenburg ARS will operate W4BFB from 1400Z-2400Z Nov.

13th, and 1800Z-2400Z Nov. 14th, to celebrate the 2nd Anniversary of the amateur radio education center at Discovery Place, the hands-on science museum in uptown Charlotte. Operation will be in the lower 25 kHz of the General 80, 40, and 20 meter phone subbands; as well as in the Novice 10 meter phone subband. For a certificate, send a 9" x 12" SASE to Mecklenburg ARS, 2425 Park Rd.-Room 023, Charlotte NC 28203-5974.

COLLEGE PARK, MD The Laurel, MD ARC will operate W3DQI FROM 1700Z Nov. 13th-2100Z Nov. 14th, from College Park Airport. Operation will be in the lower portions of the General bands, near 28.5 in the Novice subband, and on 147.5 FM. For a certificate, send QSL, 9" x 12" SASE, and your QSO nr to LARC, P.O. Box 3039, Laurel MD 20709-0039.

STUART, FL Martin Co. Ares/Races will operate WA2TRJ 1400Z-2200Z both days, from the 6th annual Jensen Beach Pineapple Festival. Operation will be on the lower portion of the General 10, 15, and 20 meter bands. For a certificate, send QSL and a 9" x 12" SASE to Larry Cohen WA2TRJ, 5595 SE Lamay Dr., Stuart FL 34997.

NOV 19-21

FORT LANGLEY, B.C., CANADA The Fraser Valley ARA will operate VF7L from Fort Langley, to commemorate the 135th Anniversary of the Proclamation read by Sir James Douglas at Fort Langley, Nov. 19, 1858, creating the Colony of British Columbia. Operation will be on the 20, 15, and 10 meter bands in the General portions, from 1700Z to 2300Z over the 3 days. For a certificate, send QSL and a 9" x 12" SASE (or \$1 to cover postage), to Fraser Valley ARA, Box 50, Fort Langley, BC, V0X 1J0 Canada.

Fast Packet Ticket!

The PackeTwin™ Wireless Communications System

Thinking about the move to packet radio? Or have you already tried 1200 baud packet only to become quickly discouraged?

At Gracilis, we've got the ticket to the kind of speed you're looking for.

Using our PackeTwin system with your existing IBM®-PC or compatible, you'll easily be able to communicate with other packet radio stations at rates of 9600 or 19,200 baud. If higher speeds are desired, the popular WA4DSY modem can be constructed and added to provide operation at 56,000bps.

When you order our PackeTwin Wireless Communications System, you'll get a plug-n-play 9600/19,200 baud system, complete with modem and palm-size two watt UHF transceiver. You supply the PC and antenna—We supply the rest!

Consider these important features...

- Exclusive use of the PC's DMA channels provides an upgrade path to 1Mbps
- A second channel is included that can be used to provide a separate RS-232 or RS-422 interface
- Free software provides access to AX.25 and TCP/IP networks
- Free firmware updates

For information contact your distributor, or...

NEW PRODUCTS

Number 22 on your Feedback card

Compiled by Charles Warrington WA1RZW

MULTIFAX

The new MultifAX external WEFAX demodulator is now available, and it can be used anywhere with an IBM or compatible PC, Laptop, or Notebook. The unit interfaces directly through the

parallel printer port; it does not require its own internal slot.

This external unit uses the same software and supports the same features as the popular MultiFAX Version 2.2 plug-in card. The unit runs on any 12 VDC supply, including cars and boats. Now you can downlink NOAA satellite weather imagery wherever you go.

The price is \$389 plus \$8 S & H in the U.S. (The unit is shown with its cover removed.) For further information, contact: *MultiFAX 143 Rollin Irish Road, Milton VT 05468; (802) 893-7006, FAX (802) 893-6859.* Or circle Reader Service No. 202.

PAKTEK

PAKTEK has introduced the "Tool Tote" as their unique solution for the two biggest complaints about hard utility boxes: 1) They are clunky; and 2) They damage surfaces. The new-fashioned Tool Tote is strong but gentle.

This handy soft-sided utility organizer features an over-sized center compartment opening for easy access, 14 external pockets, an extra-large zipper with two pulls, bold red and black styling, and an affordable price of \$24.97.

For more information or to place an order, contact: *PAKTEK, Inc., 7307 82nd St. Ct. SW, Tacoma WA 98498;*

(800) 258-8458. Or circle Reader Service No. 201.

JADE PRODUCTS, INC.

Here's the latest addition to Jade Products FUN-KIT line: the 160 Meter Twin-Lead Marconi Antenna. This antenna (Model AN-00001-01) is a complete, ready-to-install kit consisting of all the necessary hardware, wire, twin-lead, connectors, and support rope.

This antenna provides unique support for the twin-lead, thus preventing the failure due to fatigue and flexing which often occurs when hanging twin-lead by rope. This elbow support forms a gradual bend, and is adjustable. The antenna is approximately 126 feet long. With the elbow elevated to 35 feet, the horizontal section would require only 90 feet.

Installation and connection is simple; an antenna tuner is not required.

The price is \$39.95. To order or for more information, contact *Jade Products Inc., P.O. Box 368, East Hampstead NH 03826; (603) 329-6995.* Or circle Reader Service No. 206.

S-COM INDUSTRIES

S-COM Industries is now shipping a powerful 100-setpoint scheduler as a standard feature on all 5K Repeater Controllers. The scheduler executes user-defined macro commands at programmable setpoints (times and dates). The macro commands determine the action the controller will take, such as changing repeater access modes for day and night, and reprogramming the identifier for holidays and special events, etc. These can be set for a specific time and date, or for events recurring on a regular basis.

The controller automatically com-

NCG COMET

New from Comet, this compact Cross Needle SWR/Power Meter has its metering separate from its RF sensor. Three models are available for high power HF, low power HF/VHF, and low power VHF/UHF. The Cross Needle design provides forward and reflected power and VSWR simultaneously.

Three-switch selectable power ranges are provided on each model, with a fourth switch to measure DC voltage from the power supply or vehicle. The meter is lighted in color for easy reading.

The CMX Meter Series is specifically designed and ideally suited to mobile operation. Each meter comes with a standard six-foot cable allowing placement of the meter head near the

rig's remote head, while the sensor near the rig itself. An optional 10-ft extension is also available.

The CMX Series is available from your amateur radio dealer. For more information contact: *NCG Company 1275 North Grove St., Anaheim CA 92806; (800) 962-2611, FAX (714) 630-7024.* Or circle Reader Service No. 204.

P.C. ELECTRONICS

Here's a low-cost progressive way of getting into ATV: the P.C. Electronics Model TX70-1b 1.5 watt 70 cm (420-450 MHz) Transmitter. Many start by purchasing the \$89 TVC-4G Tunable Down Converter just to check out the local ATV repeater or simplex action. After the ATV bug bites, they are ready to transmit back. But now, instead of trading for an all-in-one-box transceiver, they can just add the companion TX70-1b Transmitter for \$279.

The transmitter's rugged die-

cast aluminum case is lightweight, less than two pounds, and is strong enough to easily fit in a knapsack. The unit comes with one crystal that has provisions for switching between two frequencies. The external power requirements are 12 to 14 VDC at 5 mA. The antenna connector is a TNC; a BNC outputs to the receiver down converter from the built-in power T/R relay.

No-code Technician Class or higher amateurs are welcome to write or call for a 10-page catalog. Please contact: *P.C. Electronics, 2522 Paxson Lane, Arcadia CA 91007; (818) 447-4565.* Or circle Reader Service No. 205.

ANTENNA SPECIALISTS

The Antenna Specialists Co. has developed a new set of software programs to aid communication system designers and operators in producing critical base antenna calculations and patterns tailored to their own system requirements. Called the RF Tools Series, the programs are said to be both highly accurate and easy to use.

Disk 1, called DXPLOTT, permits precise calculation of beam tilt coverage,

penetrates for power outages and leap years. The 5K Repeater Controller is priced at \$175. Options and upgrades for older models are available. For

Disk 2, called PATPLOT, calculates and plots digitized base antenna patterns. Disk 3, called ANTIPLOT, develops patterns for side-mounted base antennas. These programs are available on 5-1/4" IBM compatible disks, but the programs can also be downloaded, free of charge, from the manufacturer's remote bulletin board system (RBBS). The A/S RBBS is online 24 hours a day and offers

an enormous bank of technical product information, files capability, and help utilities, and listings of technical and engineering support staff. The modern communications mat is 300/1200/2400/9600-N81. Number is (216) 349-8698.

For further information contact: *Antenna Specialists Company, 30 Bruce Industrial Parkway, Cleveland OH 44139-3996; voice (216) 384-000, Fax: (216) 349-8407.* Or circle Reader Service No. 203.

For more information, contact: *S-COM Industries, P.O. Box 1718, Loveland OH 43039-1718; (303) 663-6000.* Or circle Reader Service No. 206.

David Cassidy N1GPH

Giving Thanks

It is approaching that time of the year when we are supposed to reflect upon our lives, and ponder the things for which we should give thanks. When I sit down to that Thanksgiving meal, here are some of the things that I'll be giving thanks for.

First and foremost, thanks to Wayne Green for his continued trust, guidance and example. I have learned more about marketing and publishing in the last three years than I did in the previous 10. We don't just talk about things here at WGI, we do them. It is Wayne's leadership that fosters this type of entrepreneurial spirit, and makes it a pleasure to come to work in the morning.

I also need to thank the staff of 73. Less than a dozen people put out this magazine (as well as *Radio Fun*), and I can honestly tell you that I have never worked with a more talented group of people (and I've been lucky to have worked with some pretty talented folks). We are truly a team, and I think it shows in the quality of our magazine. I hope you agree.

"Lots of people won't admit it, but the no-code license has single-handedly kept the amateur radio industry from feeling the worst of the economic difficulties of the last few years."

Thank you to the columnists and writers who grace us each month with their talents. I am continuously amazed at how good our writers are! I truly believe that 73 has the finest group of columnists and regular contributors of any magazine in the electronics field. If you doubt me, go ahead and do a side-by-side comparison with any other magazine. It ain't bragging when it's true.

Thank you to the ARRL. Yup... I said the ARRL. Regular readers of this column might be asking themselves, "Why is Dave thanking the organization that he spends so much time criticizing?" First of all, I am *not* anti-ARRL. I believe that the League is the only organization that is capable of representing the interests and ensuring the future of amateur radio. I just wish they would do it! I'd like to thank the gang in Newington for providing me with so much material over the last few years. We can only hope the day will come when this will no longer be the case.

We should all thank the FCC for the new Technician Class license. While we're at it, let's send a hearty "thanks" to all of the Techs (and all the other newcomers) who have received their licenses this year. Lots of people won't

admit it, but the no-code license has single-handedly kept the amateur radio industry from feeling the worst of the economic difficulties of the last few years. The no-coders have also revitalized many ham clubs across the country. Contrary to what the Tech-bashers have been crying, those who have entered our ranks via the Technician Class license are learning the code and upgrading at a phenomenal rate. Take a good, hard look folks, because this is the future of amateur radio.

Thanks go to the companies who advertise with us. I have never worked in an industry where I consider so many business associates friends. We've had quite a few advertising success stories over the last few years, and I'm happy that more and more companies are waking up to the fact that 73 readers are their biggest source of potential customers.

Thanks to the 30,000 (and growing) of you who send us your \$20 every year to subscribe. It is for you that we fight deadlines, scrutinize every word, draw figures, paste up ads... and

then do it all over again 30 days later. Your letters tell us that you appreciate our efforts, and you let us know when we've fallen short of our own high standards. More thanks to the over 20,000 (and growing) of you who plug down your \$2.95 every month to buy 73 on the newsstand.

Thanks to those of you who take the time to stop by the 73 booth at hamfests. You have no idea how helpful it is to have face-to-face discussions with our readers... and our non-readers. You remind us that, more than most magazines, the relationship we have with our readers is a phenomenon in the publishing industry. That goes double for *Radio Fun* readers. It is a relationship that we here at the home office truly cherish and strive to live up to.

Finally, thanks to all of you who read "Random Output," especially those who choose to write and comment on my monthly musings (even those who think I should shut up and stop bothering people). Your opinions are of vital importance, and it helps immeasurably to know what you are thinking. A magazine column is so often a monologue. You folks make it more of a dialogue, and that makes all the difference.

Jim Gray W1XU

Jim Gray W1XU
210 East Chateau Circle
Payson AZ 85541

You can expect November conditions to be generally Fair (F) to Good (G) this month, except for the week between the 16th and 23rd when conditions are expected to be Poor (P) to Very Poor (VP), particularly on the 18th and 22nd. During this week there may be geophysical disturbances in the atmosphere as well as the ionosphere, so be aware of possible heavy storms of rain or snow and other effects such as volcanism, earthquakes, and the like somewhere on earth. Pay particular attention to your local radio and TV stations during this week with announcements of local weather conditions.

November is a month when propagation is trending from the generally good DX outlook of September and October to the generally poorer DX conditions of November, December, and January. The higher frequency bands above 20 meters are likely to close early (at sunset or shortly thereafter), and the lower frequency bands below 20 meters will be open after dark and until the early morning hours. Except for the days on the chart marked Poor or Very Poor, you will find the low atmospheric noise and the wide-open 160, 80, 40, and 30 meter bands to be a big change from summer and fall.

As you know, the sunspot numbers are declining each month, with only an occasional spurt of solar flux above the 100 level. The sunspot minimum is now predicted for sometime in late 1996 or early 1997... with a good possibility that an even earlier minimum may occur. During these times of sunspot inactivity there will be fewer openings for DX on the HF bands. Keep an ear open for DX to Europe in the morning hours local time, and to the Pacific in afternoon hours on the 10, 12, 15, and 17 meter bands. Midday openings to South and Central America and Africa may be possible on some days

this month. Short skip within the U.S. will prevail on Good (G) days. The meter band will be the mainstay of DX this month, with occasional surprises on the higher bands. Twenty v show openings to all parts of the world on Good (G) days until well after dark.

The 40 and 80 meter bands (and meters, too) will be very good for DX to Europe in the evening hours, and the Pacific during the early morning hours around sunrise. Eighty meters may well be the choice of DXers for the next couple of months, so make sure your antennas for these bands are running at optimum performance.

On 160 meters, there will be little activity until around sunset and aft throughout the evening hours a peaking toward Europe around midnight. Openings to the Pacific and south and west will be best around sunrise. You will enjoy very low atmospheric noise and strong signals. See you next month!

FEEDBACK... FEEDBACK!

It's like being there—right here in our offices! How? Just take advantage of our FEEDBACK card on page 17. You'll notice a feedback number at the beginning of each article and column. We'd like you to rate what you read so that we can print what types of things you like best. And then we will draw one Feedback card each month for a free subscription to 73.

Contract: You have stumbled into the pages of 73 magazine. You are now in our evil clutches! Now get to work on a home-brew project! We don't mean chugging frosty beers in the living room; we mean singing solder. So, find a project you would like and get going.

NEVER SAY DIE

Wayne Green W2NSD/1

Spending Money is a Lot More Fun . . .

. . . than making it. That's the hard part . . . at least for most of us. So wouldn't you like all the guidance you can get to help you spend your money wisely? I really hate it when I get suckered, don't you? Well, you can help me and the rest of us who might blunder into some sucker bets by giving us the benefit of your experience . . . happy or sorry.

Here's the drill. Whenever you buy any ham product . . . a transceiver, HT, antenna, book, gadget, and so on, check it out carefully and then let me know how much you'd recommend it, on a scale of one to 10, as something you think the rest of us ought to buy. Give me your call, your recommendation, your age, and how long you've been a ham. You might send it on a QSL card, a page torn from your old spiral notebook, via the 73 BBS, CompuServe, MCI, fax, or whatever. No, never mind the whatever.

If you've bought one of the ARRL books, how is it? How about the new CQ videotapes? I was surprised at how good they are. What do you think? I'm still trying to decide what rig to get for my new ham shack and so far you haven't been a lot of help. Look, I tell you when I find things I enjoy and think are a good deal, so what's wrong with you reciprocating? I might even pass your rating along to help other readers get the most from their money.

One to 10, with one being absolute garbage . . . like a certain KV4 I could name . . . and 10 being heavenly bliss . . . like my Scott Kirby CDs of Joplin's music. By the way, 99% of you have disappointed me far beyond my ability to express myself . . . and you have to admit I'm pretty good at that . . . by not yet buying one of Kirby's Joplin CDs. I've thought it over carefully and decided that Scott Joplin was the most creative composer America has ever produced. Yes, he was black. What are you, a bigot? This came to mind because Volume 4 of "The Complete Joplin" is now available. This is the last of the series.

Just as I try to get you to enjoy all the different things we can do in amateur radio . . . things that I've enjoyed

. . . I've been trying to get the readers of my *Secret Guide To Music* to try the music that I love the most. And I've been succeeding pretty well. I've gotten thousands of my readers into Joplin's incredible music, and even converted thousands of rock fans to enjoying classical music, too. Do you have a CD player yet? There must be some music you enjoy listening to. So get a player and take a little time to sit back and luxuriate in music that will help rebuild your psyche. Then try one of my Joplin CDs and see what happens to you.

I'm sure I've told you the story, but you've probably forgotten it. What happened was that when I saw *The Sting* around 20 years ago I loved the music and started buying every Joplin LP I could find. But the more I listened to them, the more I knew something was missing. They all sounded too much like a player piano. I wished my father hadn't been so against my learning to play the piano when I was young. I wanted to let the beauty I could sense in the music come out.

When I got into the music business publishing *CD Review* I started bugging the record companies to look for a pianist who played Joplin right. I got nowhere. They just looked at me funny. So late one night I was walking along a street in New Orleans, coming back from a riverboat jazz concert, when I passed a grungy little bar with piano music coming out the door. Joplin! I grabbed Sherry and stopped. Hey! We went in, sat down and had a couple Cokes. There was this young kid with a ponytail playing Joplin the way I'd heard it in my heart. After a couple hours of ecstasy I knew I was in the record business. Yes, I knew that 95% of all records lose money. I didn't care. People just had to hear this. It was a mission.

So we bought Scott Kirby to New Hampshire and recorded a CD of Joplin's music. Sherry found a nice old Steinway piano in the Peterborough Unitarian church, and by luck I had an experienced recording engineer working for me. We got Knud Keller KV4GG, who had been my bookkeeper for years, to keep the old piano in tune. Knud used to be a concert pianist in Stuttgart before getting practical. I paid him off with a new ICOM rig.

Kirby, 24, was an Ohio State graduate, with a good solid classical music background. But he loved Joplin's music so much he moved to New Orleans from Columbus, bought a piano, put wheels on it, and played Joplin's music every day on the streets. As far as I know, Scott is the only person in the world making a steady living playing ragtime. There are one or two chaps playing ragtime in the Disney parks, but they're part-time. Kirby turned out to be one of the nicest guys. Despite his stupendous talent, he's unassuming.

The church was a difficult place to record. Every time a truck went past on Route 202 Scott had to stop and start over again. He and David Torrey, the engineer, got to recording after midnight to avoid these interruptions. So when we wanted to do a second CD we had Knud look for a better piano, one we could set up in the garage at my farm, using that as a studio. Knud found a wonderful 1898 Steinway upright. Great sound. Then he found an 1896 Bradbury upright concert grand, which was even better for some of the rags. The Steinway was great for the concert pieces. David set up sounding boards to liven up the garage and Scott did another CD. He liked the new pianos so well we decided to start this new CD as Volume 1 of a set of four CDs of the "Complete Joplin" rags, marches and waltzes.

About this time Phil Martus, from the circulation department, got to helping clean out my barn. He did a marvelous job. I looked at the huge space he'd cleared and thought we had room to build a recording studio. David designed it and Phil, with his brother Greg, built it. The end result was something you ought to see if you ever get up this way. It's state-of-the-art digital. Artists who've come here from all over the world to record tell me it's the finest studio in the country. Scott did Volumes 2, 3, and 4 in the new studio.

Now that he's done all of Joplin's music he'll be coming up to record some good rags by other composers. But most of all I want you to hear the wonderful rags that Scott's written.

Since appearing on my Greener Pastures Records, Scott has been invited to play at the major ragtime festivals around the country. He's knocked

'em dead! When he finishes playing there's a silence and then the audience gives him a standing ovation. No one else gets that, and there are some famous ragtime performers at these shindigs. If I get you hooked on ragtime, which I hope I can, you may be getting together with me at festivals in Sedalia in June, Boulder in July, and Fresno in November.

I hope you'll excuse me for coming on like this, but since most of you have been reading my stuff for years, I think of you as friends I write to every month, not as subscribers. So I share my enthusiasms and frustrations with you. I haven't told you, but when you take the time to write back, I enjoy reading what you've got to say. I try to answer, when I can, but I can't answer everyone. In my music magazine I ask my readers to let me know if they find a CD which they think I'll enjoy . . . and I do the same for them.

So that's why I'm after you to try your hand at 10 GHz, where I had so much fun making contacts with Chuck Martin WA1KPS in seven different states. That was so exciting I didn't want you to miss out. Ditto if you can make it on a DXpedition somewhere. These are things you'll remember the rest of your life with pleasure.

That's one thing I like about music . . . once you get a record you'll always be able to enjoy it. Don't get me started! I feel the same way about books. Hey, you really ought to read this one! Well, I can't get you into my living room and play my favorite CDs for you or walk you through my library, pointing out the books that are the most fabulous. I can't even get out my slides and show you how exciting it was to visit and operate from Sabah or New Caledonia. But maybe I can get you to try your hand at some satellite contacts. And how about getting geared up for some 2m aurora contacts this fall? I guarantee you'll never forget one single contact! And if I can get you to subscribe to my music magazine, we can share our music tastes. I'll try to get you tuned into Delius, Gliere, Ippolitov-Ivanov, and a few more. But my first try will be Joplin. Maybe I'll get you to buy the boxed set of four CDs for \$60. Probably not. But you should.

I bought my first record when I was around 12. Strauss waltzes. RCA Red Seal. Cost a buck for 10 minutes of music. That's around \$20 in today's dollarettes. Now you can buy a superb 60 minutes of music for around \$15. I've been putting out samplers for \$3.79, just to cover the postage and handling, each with an hour of wonderful music. I've over a hundred of 'em available. They're all listed in my *Secret Guide*. Each has about 15 of the best-rated tracks from recently released independent record company CDs. This is one of the best ways to shop for new CDs. There's nothing like hearing the music to know whether you're going to want to invest \$15 in a CD.

Oh, I forgot. I got all wrapped up in

Continued on page 80

From the Hamshack

William W. McConnell KD4UUB, Clover SC I live in a region where thunderstorms are frequent, sudden, and severe. I'm concerned about providing adequate lightning protection for my ham shack; however, I find that the ham literature on the subject is superficial and not very helpful.

I sent for and received the catalog from Poly Phaser Corporation, a 73 advertiser, and was delighted to find it contains lots of good information about lightning protection/grounding systems and about their products. But their information is aimed primarily at large commercial installations which are, undoubtedly, the source of most of their business.

My suggestion is that 73 commission an expert in the protection/grounding field to prepare a comprehensive article (or series) on this vital subject. I envision that the article(s) would cover the current technology and would be written specifically to cover a typical ham station.

Perhaps 73 would publish this up-to-date information on protection/grounding systems that will be definitive for ham applications.

Bill—Coincidentally, the September issue of Radio Fun features an article on the fundamentals of lightning, including dos and don'ts for the average ham and a book review for those seeking more information. This may not answer all of your questions, because lightning is still not completely understood, but I hope it helps you . . . Charlie WA1RZV.

Harvey A. Nelson N9FHO, Madison WI Wayne—OK, here's the check for my renewal.

I usually agree with most of what you have to say regarding our hobby. One instance where I disagree with you (and most of the amateur community) is on the 14.313 MHz issue. You tend to view things from the perspective of an entrepreneur (you're a good one!) . . . cost/benefit ratios, market analysis, perceived value, image, product development, etc. I work in a hospital (I'm not an MD) and tend to view issues in terms of treatable/non-treatable disease.

Suppose that your community was experiencing some sort of infectious epidemic. Suppose that doctors and public health officials tell you that there is no cure for the disease but that it can be localized and contained in a very limited area . . . say a little island in the middle of a river that runs through your town. Would you be willing to sacrifice that little island for the good of the greater community? Are you willing to accept a leper colony in your midst?

My answer, in this instance, is an emphatic YES! What we have on 14.313 MHz is a spot where a good

portion of the "crazies" have decided to collect themselves. Without prodding from the rest of us, they have found their fellows and are busily feeding on one another. That leaves the rest of the band open for our more pleasurable activities. There should be one such frequency on every band. We can avoid being "infected" by using our receivers properly . . . a trick I learned in my old TV-watching days: The big knob changes the channel and one of the little knobs usually turns it off. (We might include this bit of knowledge in the Extra Class question pool!)

You and I, in laissez-faire fashion, need not concern ourselves with what others choose to listen to, but with making our own conversation interesting enough to attract our own following . . . hoping that our insightful questioning will add to our own stores of knowledge.

But what about the youngsters? The 12- and 14-year-olds we hope to attract? Don't we have some responsibility for them? We must protect their tender ears, if not their minds . . . right?

Baloney! Those 12- and 14-year-olds, each and every one, has at least a parent who has taken on that responsibility . . . if not willingly, then by force of law. Our obligation in their nurturing is to pay our taxes to provide for their schools and to avoid hitting them with our automobiles when their parents allow them to play in the streets! Nothing more.

The parent must play as much a part in the kid's newfound hobby as the kid. The parent has the responsibility for knowing what is happening on 14.313 and monitoring his/her child's activities . . . the same responsibility they have for monitoring what books and magazines the kid reads and what movies and TV programs the kid watches (hopefully not many!). When the kid blunders onto the frequency, the parent will have to explain what the "cancer" is all about and how to cope with it.

You might want to provide parents with the insights they will need (as a part of your business venture). How about sending a nice letter/pamphlet to the parents of the newly licensed young ham, explaining some of the more unattractive aspects of our hobby, along with complimentary copies of your rags? After all, mom and dad are most likely paying for the kid's magazine subscriptions.

For my own part, I will encourage youngsters to begin their ham careers in digital modes . . . there ain't no backspace key on a tongue or microphone.

The only problem with that, Harv, is to figure out how we can keep the

FCC Commissioners from hearing the baloney on 313, and thinking that we're all like that . . . Wayne.

Fred Carmichael KD4ATW, Chattanooga TN Reading Wayne Green's "Never Say Die" columns in August and September, and David Cassidy's "Random Output," has encouraged me to voice my opinion of the No-Code Tech license and the license procedure.

I am 47 years old and ever since I was 12 years old I wanted to be an amateur radio operator. I took the test the first time when I was 12 years old, and have taken it four times since. Each time I failed because of not being able to receive the code. However, two-and-a-half years ago I passed the No-Code Tech. I have had a great time since, operating 2 meters, 70 cm, and packet. I enjoy packet the most because it involves three of my loves: amateur radio, computing, and bulletin board systems. If it weren't for the No-Code Tech, I would not be writing this letter. I am currently working towards my General, but once I pass I will only use the voice bands, not CW.

We need young people in our ranks of amateurs. Young people are not interested in learning code, but most are interested in computers and other digital modes.

I agree with both Wayne and David in that we need to change the license structure and testing requirements if amateur radio is to survive. I suggest that we have two classes of licenses. The first would be for 10 meters and below; the second for all above 10 meters. We could call the first class "Amateur" and the second "Amateur Extra." To take care of all the old folks who like relics (code), we could do like the present system: Tech and Tech Plus. Next we would need to change the test to cover the FCC rules: operating practices, and how to properly use your radio equipment. The code side of the test would be optional, with 5 wpm for Amateur Plus and 13 wpm for Amateur Extra Plus. This way, if you wanted to use the relic, you could take the optional code test to get you Plus. Code would not be a requirement.

I have read articles and heard everyone talking about amateurs needing to change, getting younger people involved, and moving into the 21st century and not clinging to the past. I also know that making the changes I have suggested would require some changes internationally, but why not make these changes?

Peter A. Bergman NØBLX, Brainerd MN Wayne—I agree completely that something is wrong with education in America. We have "Honor Students" who cannot find their town on a map and have trouble with arithmetic, forget trig or calculus.

Much of the problem comes from the fact that "fashion" sweeps through the educational establishment and, once in vogue, some of the ideas are almost impossible to dislodge. Cur-

rently, it is considered nasty to make kids memorize. This bit of nonsense has been around long enough that memory skills and the teaching of them is almost a lost art.

Another educational jewel is called "process not product." The followers of this one believe that if children are taught how to think—always an admirable goal—they will derive the facts for themselves. Rather like making bricks with straw, not clay. If you want a challenge, try teaching science out of a "P not P" textbook.

I enjoyed your thoughts on getting something for our foreign aid. Why not use the idea a little closer to home? Let's buy Haiti—if we can figure out who the government is. It would give us a place for an open market enclave close to the US, also perhaps a location for a large HIV sanitarium and save the Haitians wishing to live in the US a dangerous boat trip.

By the way, I have a college degree in education. I'm also dyslexic and have ADD. Sr. Mary Margaret didn't know about them so she just made me work harder instead of giving me an excuse for failure.

I don't teach anymore; I drive a cab for the handicapped. It's less frustrating.

Lavee Israel 5NØSVL/4X1UF, Lagos Nigeria Wayne—It's a pleasure to read your magazine after a pause of several years. I especially love to read your editorials, and I like them very much. In most cases I agree with you 100%. It is a pity, however, that people are so narrow-minded and stubborn, especially when they have to dictate to others what to do.

For the past two years, the recession in Israel has pushed me to do business in Nigeria, where I deal with commercial two-way radio, combining it with my hobby, operating as 5NØSVL. We are trying very hard to help as many youngsters as possible to join the hobby and I would like especially to mention Kunle 5NØQBA, Peete 5NØCEP and Musa 5NØSAI. If we need contributions of used radio gear, Peete tries to help us. If it's for VHF repeaters, we keep trying, sometimes in a hostile environment . . . but usually we are able to accomplish the goal. Your editorial from August is encouraging because it points out that we need to bring in as many young people as possible because this is the future, and not only in Nigeria. It applies to Jordan as well as to Israel, too, since that government is making the same mistakes. Maybe the only one doing it the right way is Japan, as you mentioned.

There are many club stations in Nigeria, and we have a weekly net every Sunday morning at 0800 on 7065 kHz. What we are trying to do is find as many surplus SSB radios as possible so those clubs can operate on this frequency.

It is very good to read your excellent magazine again. Keep up the good word and keep saying the right things.

Government Launches PCS Era

The Federal Communications Commission has allocated 160 MHz for the new PCS (Personal Communications Service) in the 2 GHz band. The decision is expected to spark intense competition to deliver wireless services.

The FCC plans to use auctions to award PCS licenses. Local telephone companies are seen as the big losers in the decision. The new PCS service will compete with the cellular telephone industry and will carry data, video, and voice transmissions.

What this will mean to the future of ham radio is anyone's guess. Some are already speculating that PCS will be to the 1990s what the cell-phone was to the 1980s. One lightweight portable communicator could soon serve you at home, at work, and in your car. Your phone number would follow you wherever you go. The system can deliver reliable communications to portable phones, FAX machines, and pocket computers.

The Clinton Administration hopes to generate as much as \$10 billion for the treasury from frequency auctions. By the year 2010, 60 million subscribers could generate up to \$40 billion in revenue. *TNX Electronic Engineering Times, Issue 765, Sept. 27, 1993, and W5YI Report, Issue 19, October 1, 1993.*

ICOM Is Dealing

ICOM America is for the first time offering discount coupons for a variety of products that complement ICOM radios. Anyone purchasing a new ICOM radio between now and December 31, 1993, will receive a book of 32 coupons from 21 leading manufacturers who sell products and accessories.

ICOM's Chris Lougee says, "Virtually every time someone buys a new radio, they need additional components to go with that radio. ICOM is taking a leadership position in identifying complementary products and making arrangements to sell those products to consumers at a significant discount. We believe it will broaden the appeal of amateur radio."

High-Tech Highway

The Clinton Administration's Information Superhighway Plan is starting to take shape. The NTIA (National Telecommunications and Information Administration) will be given the lead role in its formation. The government's strategy calls for competing multiple cable, telephone, and computer networks.

Commerce Secretary Ron Brown will steer an industrial advisory council. You can expect major modifications to existing cable legislation and telephone restrictions. *TNX W5YI Report, Issue 19, October 1, 1993.*

Confirmation Likely

Communications attorney Reed Hundt is expected to be confirmed as the new FCC Chairman. Hundt was well received in his initial confirmation hearing before the Senate Commerce, Science and Transportation Committee.

The 45-year-old Hundt is a partner in the

Washington law firm of Latham & Watkins, and he enjoys the friendship of Vice President Al Gore. Hundt has supported increased competition in the telcom industry and universal access to new information technologies overseen by the FCC. *TNX Electronic Engineering Times, September 27, 1993.*

Canada Loves Its Hams

A seven-page full-color spread titled "Loud and Clear" graced the pages of *Canadian Geographic* magazine's September/October issue. The feature article paints a sparkling picture of amateur radio operation in the Dominion.

The story was written by Janice Hamilton VE2JHJ and photographed by husband Harold Rosenberg VE2HRP. Rosenberg says, "I feel that spreading the good word about ham radio is very important, especially in the mainstream press." *TNX ES FB VE2HRP, VE2JHJ, and The Royal Canadian Geographical Society.*

Technical Opportunities Knock

There will soon be far fewer opportunities for blue-collar workers, and a lot more for those who possess technical expertise, according to an expert quoted in *Electronic Engineering Times*. Dennis A. Swyt, a technical manager at the Institute of Standards Technology, painted a picture of an America where engineers and skilled technicians will gain influence and power.

Swyt delivered his remarks to the Engineering Workforce Commission. He added, "The most important occupation group in the U.S. today, and continuing in your lifetime and your children's lifetime, is that of the technical professionals." *TNX Electronic Engineering Times, Issue 767, October 11, 1993.*

RF Standards Could Impact Hams

New RF safety guidelines proposed by the FCC could have an impact on the Amateur Radio Service. The standards being considered (at press time) are the same as those already adopted by the IEEE and the American National Standards Institute.

Possible ramifications for hams include new questions in the licensing test pool, tougher regulation of RF radiation in new products, and a heightened awareness of possible hazards from exposure to RF. *TNX W5YI Report, Issue 19, October 1, 1993.*

Making Copies

The FCC has published a "Policy on the Private Printing of FCC Forms." Under the Commission's rules, blank forms may be reproduced by private companies at their own expense, provided:

- The form must be comparable in quality to the original document without change to page size, image size, configuration of pages, folds or perforations, and matching as closely as possible the paper weight, paper color, and ink color.
- Reference to the U.S. Government Printing Office must be deleted. Except as above, do not

delete from or add to any part of the form, or attach anything to it.

- Do not add any special personalized symbols, words, phrases, or advertising.
- Be sure the current version of the form is being duplicated.

TNX W5YI Report, Issue 19, October 1, 1993.

Hams Fight Arson

Ham operators in Oakland, California, are patrolling the East Bay hills in an effort to stop a recent rash of arson fires. Four volunteer hams are on the lookout team working in cooperation with local fire authorities.

Officials hope the additional presence will help to curb the purposely-set fires. The latest list of arson cases has reminded residents of the fire storm that killed 25 people in the bay area back in 1991. *TNX Oakland Repeater Association, Oakland Tribune, and Westlink Report, No. 658, September 30, 1993.*

Mega-Micro QSO

Paul Lieb KH6HME and Chip Angle N6CA recently set a new 902 MHz terrestrial distance record of 2,469 miles (3,973 km). The CW contact, with signals just out of the noise, came at 0136 UTC on August 23.

For the next four hours, the pair tried unsuccessfully to make contact on 2304 MHz. A frequency near 144 MHz was used for the liaison. The equipment used for this historic achievement was designed by N6CA. *TNX Westlink Report, No. 658, September 30, 1993.*

Gert Alert

The Miami-based Sociedad Internacional de Radio Aficionados (SIRA) activated its emergency 20 meter net during hurricane Gert, while 100 mph winds slammed into the Atlantic coast of Central America on September 15. Net control station operator Rafael Estevez WB4ESB handled relief communications with many amateur stations as 65,000 people were evacuated along the Costa Rican and Nicaraguan coastlines. Weather bulletins issued by the National Hurricane Center in Coral Gables, Florida, were also transmitted to Central America, after being translated into Spanish. *TNX W5YI Report, Issue 19, October 1, 1993.*

Rules Change: No Big Deal

So far the consensus is there has been no significant change in amateur radio activity in the wake of the FCC's recent "Relaxing Restrictions on the Scope of Permissible Communications in the Amateur Service." The new Part 97 rules went into effect on September 13, permitting limited business communications on the ham bands.

Under the relaxed rules, hams can now make appointments, give weather report information to the National Weather Service, and order food. Fears that the VHF bands would become a pizza ordering service so far appear half-baked. *TNX W5YI Report, Issue 19, October 1, 1993.*

Deluxe Communications Audio Board

Enhance your audio with this practical add-on.

by David Curry WD4PLI

Have you ever wanted to improve the audio quality of your old receiver? Would you like to add technical improvements to a modern receiver? Though state-of-the-art ham transceivers and communication receivers have improved audio design, there are many benefits to building your own auxiliary audio section and implementing it to your receiver. Or, for the truly ambitious, use it as part of your own home-brew communications receiver.

The strategy here is to simply add several audio processes in series to achieve an improved audio output signal. My desire to design something like this was purely selfish. I wanted my long-wave receiver (a Watkins Johnson R-1401) to have some bells and whistles like my Kenwood TS-430S. I'm also in the process of building my own receiver for LF, and I wanted a good audio section to follow the RF section. This audio board will do both nicely.

The first section of the audio stages is an adjustable bandpass filter, providing control of either the frequency or the bandwidth without changing the volume or other parameters. The original bandpass filter circuit appeared in the December 1992 issue of *RF Design*, in an article written by Jefferson Hall and Alvin Connelly. It was an excellent article and I quickly built the circuit, much to my satisfaction. After a short time, however, it was apparent that more circuitry was needed to eliminate a carrier that was within the passband, so I added a simple notch filter. This very effective design was by Randy Seden WD6ELU. The combination of a notch filter and variable bandpass filter can improve receiving conditions, but for weaker signals more circuitry is required.

An additional circuit that adds this improvement, especially for CW, is a regenerative audio stage with adjustable frequency and "Q." This type of circuit has been virtually left behind in modern radio equipment,

yet it offers many advantages, considering its simplicity. One of the greatest things about a regenerative or Q-multiplier is the ability it has to reject noise and to peak the desired signal. As the regeneration is increased, the sideband noise drops, which improves your signal-to-noise ratio. The final addition to the audio board is what I call a "digitizer" circuit, which eliminates background noise for CW signals. This is nothing more than a comparator used as a variable threshold detector. The digitizer compares the audio signal to a voltage reference, and provides a square-wave or digital output. The comparator will sometimes trigger on noise that just crosses over the threshold point, so a second comparator is used as a "window," allowing the digitized CW signal

Photo A. The Deluxe Communications Audio Board.

(which is stronger) to pass, but not the weaker noise pulse. Low-pass filtering is used to clean up the square-wave signal to a more natural tone. Finally, an audio output circuit that has appeared in virtually every radio handbook was chosen for the speaker section.

I originally discovered the circuit in a SAMS book written by Walter Jung, *Audio IC Op-Amp Applications*. Low noise and low standby current are the hallmarks of this legendary circuit, using very common components. So let's review: A variable bandpass filter, followed by a variable notch filter, followed by a Q-multiplier, then a digitizer, then a 5 watt audio output section. WOW! With these devices in this particular order, it is very possible to do wonders with your receiver.

Circuit Description

The schematic shows a lot of ICs and parts, but don't let that fool you! The circuit is rather simple and can be followed easily at the top left corner, labeled "Audio Input." C1 is simply a DC blocking capacitor, while R1 sets the overall gain of the first section. If a very low audio signal is connected, R1 can be decreased in value to increase the gain. U1a, b, c, and d are all low-noise quad op amps, which keeps the size down. The filter frequency is adjusted with dual-gang potentiometer R7. The bandwidth is adjusted with R6, which controls the amount of feedback to U1a. The entire top portion of the schematic is the variable audio filter section.

The next stage is the notch filter located directly below U1. U2a and c sections provided a 180-degree phase shift of the frequency controlled by R13a and b. Using two sections of notch filtering provides a very deep null with steep skirts. Summing amplifiers U2b and d provide the nodal point where the phase-shifted frequency meets the original signal and is subtracted to almost zero. U2 is also a low-noise quad op amp. Output of the notch

section is applied to R24, which is the regeneration control for the regenerative preamp. The regenerative preamp is located by itself on the right side of the schematic. U3a and b make up a dual low-noise op amp and, as you can see, feedback is applied in desired amounts from the output of U3a to U3b and out to the U3a input again. C10, R27, C9, and R25 and 26 provide the adjustable frequency response for the filter. The potentiometer marked "Q" is adjusted once to allow smooth control of regeneration with R24. If oscillation develops, rotate R28 to the point where oscillation just ceases. The frequency control has a fairly wide frequency range to facilitate most CW signals. The audio signal is sampled at the output of U3a, and directed to switch S1. Normally, S1 is out or OFF, which applies the signal directly

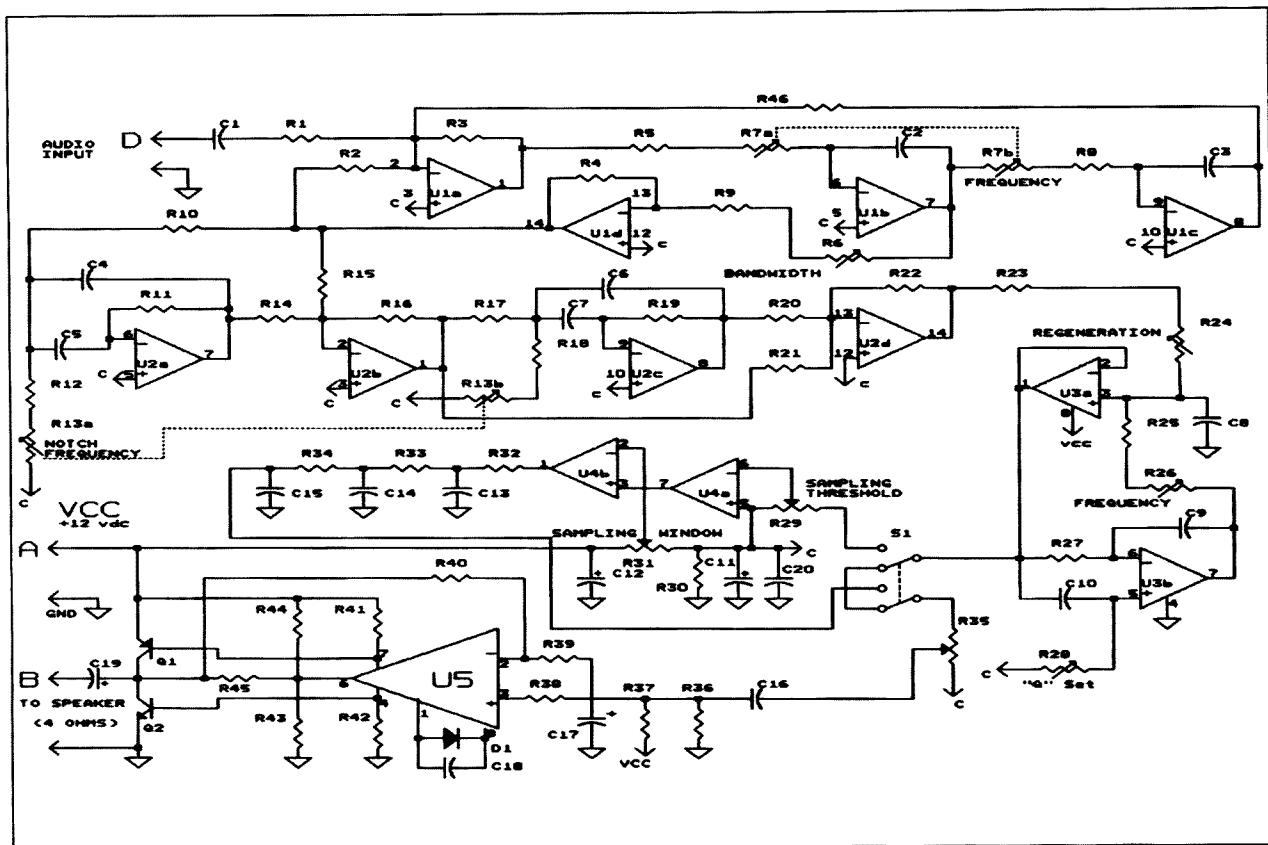

Figure 1. Schematic for the Deluxe Communications Audio Board.

to the audio amplifier stage U5. However, if the digitizer is desired, the signal is routed to comparators U4a and b. The same low-noise dual op amps are used here as with U3. Though not really intended to be used as comparators, the TI072 or LF353n op amps provide a softer comparator, making the threshold point easier to adjust. Potentiometer R29 is the input threshold control to the first comparator U4a. The signal that triggers the comparator will provide a square-wave output at U4a that is the same frequency as the input signal.

During weak signal conditions some residual noise may slightly trigger the first comparator, creating a small noise spike that is usually lower in amplitude at the output of U4a. To help eliminate this, a second comparator is used, sampling the signal that has the largest square-wave output from U4a by adjustment of R31. R31 is set to not trigger on other noise that has a lower amplitude. U4b provides us a square-wave representation of the signal to the low-pass filter. R23, R33, R34, C13, C14, and C15 comprise a low-pass filter arrangement that attenuates the high frequency components of the square wave, providing a cleaner, more listenable tone. It also lowers the square-wave amplitude to a level that can be used by the audio power amp stage. The audio power amp uses a class AB op amp to drive power transistors Q1, and Q2.

The biasing for these transistors is done

within the chip itself. This provides good audio quality at low and high volume levels since the bias is internally etched in U5. Volume is adjusted by R35. Power amp gain is set by R40. Usually there is plenty of gain to drive a common 4 or 8 ohm speaker. Diode D1 is a clamping diode to eliminate any latch-up that might occur if the speaker became shorted. C18 rolls the high frequency off just above 2.5 kHz. Resistors R43, R44, and R45 are used to set the gain and bias for Q1, and Q2. R41 and R42 are part of the biasing and power to U5.

Building Notes

The double-sided circuit board makes building this project very easy. *Remember to solder both sides of this double-sided PC board because the holes are not plated-through.* Note that potentiometers R26 and R29 are located next to switch S1 on the solder side of the board. This helps to fit more controls in a smaller space. R24 must be installed before R26. Similarly, R31 must be installed before S1, and R30 before R35. A small 5 watt heat sink is sandwiched between Q1 and Q2, and screwed securely.

Many resistors are mounted vertically on the circuit board. A small square on the layout sheet indicates this configuration. A longer rectangle denotes a horizontally-mounted resistor. Be sure to solder all pads on the component side of the circuit board that have connections to any components.

The connection points to the speaker, power supply, and audio input are marked on the layout sheet. All points marked "C" on the schematic are connected together as a common bias-point reference. There are no "C" connections to be concerned about during assembly.

Operation

Connect the speaker and the audio input cable to the appropriate points on the circuit board, then apply power. The advised minimum voltage for this circuit is 12 VDC, with up to 18 volts recommended. The higher voltage will help avoid any distortion at high volume. Turn all component-side controls counterclockwise.

Push S1 in to bypass the digitizer section.

Turn the far right hand control clockwise to a comfortable level.

The controls are in this order (from left to right on the component side): Bandpass Filter Frequency, Bandpass Filter Bandwidth, Notch Filter, Q Multiplier, Digitizer Sampling Window, Volume. Under the circuit board are: Q Multiplier Frequency, Digitizer Sampling Threshold, Digitizer Bypass Switch. Take time to experiment with these controls. The Q multiplier and digitizer controls take getting used to. Remember that with a Q multiplier you must have the frequency control at *exactly* the same frequency of the desired signal. The more regeneration you apply to the Q multiplier, the more

Figure 2. Double-sided PC board layout: a. Solder side; b. Component side; c. Parts placement diagram.

this requirement must be met. Another consequence of using large amounts of regeneration with the Q multiplier is that the CW signal becomes elongated, like a bubble. You can hear this effect distinctly. The digitizer can minimize this effect by triggering on the top portion of the elongated waveform, and then using the window comparator control to shore up the pulse width. Simply put, both controls can adjust the duty cycle when heavy regeneration from the Q

multiplier is needed. During regular operation, I recommend notching any undesired signal first, then apply the bandpass filter. Sometimes the Q multiplier works very well to improve SSB or voice communication, but over-driving with too much output volume from the receiver will degrade its ability to peak the desired signal.

Conclusion

This audio output section will provide

improved reception. It is perfect for an easy weekend project, or for someone who wants to "go all the way" and build a complete receiver from scratch. This design matches perfectly to an NE602 mixer or product detector. I would like to thank the authors for engineering these fine circuits, and Randy Seden for his computer design of the notch filter section.

Resolving 2 Meter/Cable TV Interference

A winning strategy for keeping the peace, and staying on the air!

by S.M. Yost NM8R

Is your 2m packet station in danger because of interference (TVI) it causes to the local cable TV system? Knowing your options, responsibilities, and how to track down the problem can put you back in the driver's seat. This article walks you through the entire process toward resolving this difficult issue: the technical details, how to deal with your neighbors, and how to work successfully with your cable company.

The story starts the same way, and is echoed on packet BBSs across the country: "HELP! My neighbors are up in arms, and mad as heck. I'm interfering with their cable TV. If I don't find a solution soon, my new packet station will have to go QRT. Can anyone help?"

The plea usually goes unanswered, and when it dies off the BBS, with it goes another amateur's hard-earned privilege to enjoy part of his hobby.

Worse, it's not only packet operators who can suffer. Amateur-caused cable television (CATV) interference can rear its ugly head during 2m FM voice operations as well. So, even if you're not packet-equipped (and shame on you if so!), read on . . .

W/2m CATV INTERFERENCE
ENTER MESSAGE/ CTRL-Z TO END

OM—Pulled the message about your CATVI problem from the Bulletin Board tonight. I understand your frustration, but hang in there; this problem can be solved! I had the same difficulty here. I fixed it, though, and I'm still on the air, with happy neighbors to boot. It takes three steps to solve this matter, so let's get started. First, you need a little background.

Long ago it was established that every radio service—commercial, government, and amateur—had its own frequency assignment. These assignments were formed into an orderly structure throughout the radio spectrum. A latecomer, however, called cable TV, added a silent partner to the plan. Silent, because cable TV's coaxial media (versus the ether used by the original ten-

ants) ingeniously allowed room for coexistence. Coax allowed two worlds, the off-air services and CATV, to occupy the same spectrum, separated by only a few mils of copper braid. One is free to roam the ether, while the other exists only within the confines of a coaxial cable. When everything works properly, one never knows the other exists.

Shielding—the basis for this coexistence—is the issue in your case. Because CATV runs a shielded, closed system, it is permitted to borrow frequencies already in use by other services. Nothing leaks out to QRM the off-the-air users, and conversely, nothing gets in to interfere with the CATV system. This may be great in theory, but how does it stand up in practice?

Photo A. Your foot survey for CATV leaks is easy and can be low profile. Who would suspect that this amateur operator (N8HGM) is sniffing out a CATV leak in her neighborhood, rather than just grooving to a tune on her Walkman? Conducting your leak survey while driving is also very effective, but don't forget to pay attention to the road!

Where the Rubber Meets the Road

Unfortunately, there are many things which can degrade a CATV system's shield integrity. When this happens, the door is opened for signals from the outside to get in, and for cable signals to get out. You didn't mention it, but I'll bet the interference is *only* on CATV channel 18, and *only* when you are on 2m. (I'll bet your HF gear, the "traditional" television interference source, isn't guilty at all this time.) Further, I'd wager it's not a harmonic or spurious output from your 2m rig. Consider this: Cable TV assignments are spread throughout the VHF and UHF spectra. They not only share the traditional TV band plan, but also many frequencies *around* it. All told, CATV signals occupy frequencies already in use by aircraft, broadcast TV, public safety services, and VHF amateur radio. Specifically, the video portion of cable channel 18 is centered at 145.25 MHz . . . get the picture?

A cable signal is very weak in relation to the signal you can accidentally inject with your 45 watt, packet-equipped 2m station. Once your signal gets in, it's not even a fair match! Plus, it doesn't take much of a CATV shield breach to let in an ample amount of renegade, 2m energy.

The Open Door

After you've pondered that for a moment, you should be wondering: "If my problem is one of getting into the cable system, why even mention their signal getting out?" The reason is simple: This is where the shared spectrum concept comes to the unexpected relief of amateurs. The shield break that is letting your 2m signal in is spraying wide-band video signals over the nearby area. The FCC takes a dim view of cable TV leakage, and for good reason. They don't want jumbo jets thrown off course by escaping "I Love Lucy" reruns! As a result, the FCC requires that cable companies check their systems for leaks, to prevent this. Also, limits are set on the amount of radiation permitted to escape from a CATV system. Lastly, the FCC requires prompt action to resolve leaks.

That covers the theory part. The second step of the three-part plan is foot patrol. Basically, what you'll be doing is scouting your

2WAY RADIO SERVICE MONITOR
COM-3, the world's most popular low-cost service monitor. For shops big or small, the COM-3 delivers advanced capabilities for a fantastic price—and our new lease program allows you to own a COM-3 for less than \$3.00 a day. Features • Direct entry keyboard with programmable memory • Audio & transmitter frequency counter • LED bar graph frequency/tone deviation display • 0.1-10.000 µV output levels • High receive sensitivity, less than 5 µV • 100 kHz to 999.9995 MHz • Continuous frequency coverage • Transmit protection, up to 100 watts • CTS tone encoder • 1 KHz and external modulation.
COM-3 2 Way Radio Service Monitor.....\$2995.00

SYNTHESIZED SIGNAL GENERATOR

Finally, a low-cost lab quality signal generator—a true alternative to the \$7,000 generators. The RSG-10 is a hand working, but easy to use generator ideal for the lab as well as for production test. Lease it for less than \$3.00 a day. Features • 100 KHz to 999 MHz • 100 Hz resolution to 500 MHz, 200 Hz above -130 to 10dBm output range • 0.1 dB output resolution • AM and FM modulation • 20 programmable memories • Output selection in volts, dB, dBm with instant conversion between units • RF output reverse power protected • LED display of all parameters—no analog guesswork!
RSG-10 Synthesized Signal Generator.....\$2495.00

SYNTHESIZED AUDIO GENERATOR

DDS (Direct Digital Synthesis) technology brings you a terrific audio generator at a fantastic price! Generates from 0.01 Hz to 50 KHz with live digit LED display of frequency. Sine and square wave output adjustable 0-1 volt p-p. Frequency selected by direct keyboard entry and with handy continuous tune knob. Crystal controlled accuracy of 10 ppm and two memories for rapid frequency changes. Rotate that jury-rigged old generator and treat yourself to the pleasure of using a new state-of-the-art SG-550!
SG-550 Kit.....\$169.95...SG-550WT assembled.....\$229.95

DIGITAL CODE SYNTHESIZER

Generate all popular signaling codes used in paging, and two-way radio. Generate DTMF, MF, MTS, IMTS, Single, Dual, S6 tone, tone remote, DPL, POC SAG, GOLAY and NEC. Two audio synthesizers with 0.1 Hz resolution and programmable duration, spacing and outpulsing. Both 600 ohm and TTL outputs for easy connection to any RF generator or scanner monitor. Get in on the profitable pager repair market with the COM-6 universal synthesizer. Fully assembled with 1 year warranty.
COM-6 Code Synthesizer.....\$895.00

MOTOR CONTROLLER

Control the speed and direction of any motor. Use our SMD-1 for those nice stoppers you see surplus, and our MSC-1 for DC motors. The stepper driver features variable speed, half step rotation, direction and power down mode, can drive most any stepper motor. Our DC driver features pulse width modulation control allowing full motor torque even at low speeds and can drive motors up to 50 VDC @ 10 Amps! Add our case set for a professional assembly.
SMD-1 Stepper kit.....\$24.95 MSC-1 DC mot kit.....\$24.95
SMD-1 SMD-1 case.....\$12.95 MSC-1 SMD-1 case.....\$12.95

LC-METER

Measure inductors from 10 uH-10mH and capacitors from 2 pF-2uF with high accuracy by connecting the LC-1 to any digital multimeter. Two pushbutton ranges for high resolution readings and we even give you calibration components to assure proper accuracy of your kit! Active filters and switching supplies require critical values, no one should be without an accurate LC meter. For a pro look, add our matching case set.
LC-1 LC meter kit.....\$34.95 CLC case set.....\$12.95

MINI KITS

Ramsay carries a complete line of low cost, easy to build, easy to use functional kits that can be used alone or as building blocks in larger more complex designs. Mini-kits include audio amps, tone decoders, VOX switches, timers, audio alarms, noise-makers and even shocking kits! Call for our free catalogue!

PACKET RADIO

Two new versions are available for the Commodore 64 (P-64A) or the IBM PC (P-IBM). Easy assembly NO TUNING! Includes FREE disk software, PC Board and Full Documentation. Kit form
P-64A.....\$59.95 P-IBM.....\$59.95 CASE CPK.....\$12.95

ACTIVE ANTENNA

Cramped for space? Get longwire performance with this desktop antenna. Properly designed unit has dual HF and VHF circuitry and built-in whip antenna, as well as external gain control and 9V operation makes unit ideal for SWLs, traveling hams or scanner buffs who need hotter reception. The matching case and knob set gives the unit a hundred dollar look!
AA-7Kit.....\$24.95 Matching case & knobset, CAA.....\$12.95

CW KEYS

Send perfect CW. Microprocessor keyer features 4 programmable memories of up to 26 words each, latched keying, dot-dash memory, variable speed from 3.50 WPM, adjustable sidetone, keying to any key and key rate. EAPOM memory keeps messages up to 100 words. You'll go silent before the key! Includes built-in touch paddles or use your own. Easy assembly and matching case set available for a nice station look.
CW-700 Micro keyer kit.....\$69.95 CMK Matching case set.....\$12.95
CW-700WT Assembled CW-700and case.....\$99.95

Resolving 2 meter/Cable TV Interference

Continued from page 18

neighborhood with a portable FM radio, so put on your sneakers!

Recon!

Though it's the cable company's job, you can track down the leak source (they call it an "egress") yourself. But why would you want to? Don't get the wrong idea—you won't fix any leak you find. That's up to the CATV company. You'll see in a moment, though, why it's helpful to know the source of the shield breach causing the leak. For now, be satisfied that it may save you some embarrassment if the source is in your own home! Before starting, however, carefully heed the following warning: *Do not trespass on other people's property* while performing your self-styled leak survey. It's not worth a load of No. 7 shot, or a tangle with a Doberman, to find the leak! Ham radio needs your picture in the local paper because you hooked up a homesick foreign exchange student with her family or ran a battery of phone patches for weary servicemen through MARS, *not* because of an article about your arrest for trespassing! 'Nuff said!

For our purposes, you can perform a leak survey handily from the sidewalk, or from your car. Don't do it from other people's yards without their permission (and even with their permission, only with great care).

So... how do you do it?

Sniffing It Out

CATV systems inject a special modulated RF carrier into their system to act as an "odorant," sort of like the gas company does. If they have a shield break—an egress—this tone-modulated radio frequency carrier, or tracer, intentionally escapes the cable and they sniff it out with equipment carried in their vans. Luckily, you can use a portable FM broadcast band (BCB) radio to do the same! Just like your nose finds a gas leak because of the odorant injected, your portable FM radio can find a cable TV leak.

Here's how to put your amateur version of the sniffer to work. First, determine what frequency the tracer is on in your area. Do this by placing an FM BCB portable radio near your own cable TV coax. (What? No CATV in your home? Then try this test with a cooperative neighbor, or even better, the one who is complaining.) Disconnect the incoming CATV coax from the TV or VCR and, with an FM radio close by, tune until you come across a raucous whoop-whoop-whoop tone. If the carrier injector is turned on, you *can't* miss it. In my area this carrier resides around 107.8 MHz, although in some locales it's placed in the middle of the FM band. Once you know the tracer carrier's frequency, drive or walk your neighborhood, listening for this obnoxious tone. (Hook the coax you pulled for this test back up, first!)

Don't be surprised if you encounter a number of cable TV leaks in your search. Not everything you will hear, however, is a leak the cable company needs to be con-

cerned about. There *is* a permissible amount of radiation, tolerated by the FCC. You'll quickly learn to sort out the weak ones from the strong ones.

Note, too, that the sensitivity of a car's FM BCB radio is greater than the squelch setting of the commercial sniffers the CATV companies use. As a guideline, you're interested in strong leaks within a few block area of your QTH. A strong leak would be one where you hear "S9" more than 50 feet from its source. I find the car radio works best for the general search, and a portable radio for pinpointing the source.

Just remember this clue, Sherlock: Where their signal escapes, your signal enters.

What to Look For

Once your sniffer has helped you zero in on a possible leak, you need to turn to your observation skills. As you drive the system, pay particular attention to pedestal junction block housings (those 12" square by 3'-high metal boxes), and any pole-mounted distribution amplifiers. Also, scan the overhead cables for any that may have been damaged by falling branches. At a residence, the leak source can be damaged or water-corroded cable, especially in the drip loop where it enters a house. Also look for loose connectors or unterminated splitters or cable runs. Devices a subscriber puts on his line, such as cheap (poorly-shielded) coax, lengths of 300 ohm twinlead(!), and game switches, can breach the system's integrity, too. One other possibility to be aware of is the illegal tap. Take the safe path and let the cable employees "discover" these.

Why go through the hassle of hunting down the leak yourself? You don't need to. But it will help, and might even favorably impress the CATV company if you can tell them where you think the egress is located. Possibly you can even guide the CATV tech, saving him time in his search.

Contacting the Cable Company

The last step toward a solution is to make contact. (This should be easy; you're a ham, remember?!) Once you're at this point, simply pick up the telephone and call the cable company.

First, some tips to make your effort more successful:

Plan what you will say *before* calling. Your goal is to get one point across, clearly: You're the one who is causing the interference (*that* will get their attention), and you want to resolve the matter quickly, to their benefit as well as yours. Speak and act professionally—it will make a more favorable impression. Ask to speak with the System Manager, his assistant, or a member of the Engineering Department. (You may prefer to visit the cable company's office and deliver your message personally. If you're the charming, amiable type, the doors will open quickly.) After you've clearly stated your reason for contacting them, run down the following list of points to discuss: Explain

the problem and how you know the things you do. (Expect them to be curious how you know about the technical aspects of their system.) Use the word egress. (They prefer it to leak; it sounds less threatening.) Did you find anything in your own search for the egress? If so, tell them now.

Have they encountered this problem be-

fore? How did they resolve it?

Keep in mind it's not always a fault of their system that causes the leak—oops, egress. It can be devices the subscriber puts on the line. They should be as interested in these, however, as defects in their own system. Either can allow CATV signals to escape, or permit outside signal entry. It's all

in how you present it.

Don't pepper your speech with ham "Q" signals. Even though we talk this way, CATV people won't find it intelligible, or amusing.

Inquire if the cable company noted any leaks in your area at their last FCC-mandated leak survey. (They refer to this survey as

CATV Frequency Assignments

Knowing what frequency is used (and shared) by a particular CATV channel can be useful in troubleshooting CATV problems. Table 1 can help you determine CATV channel frequencies from the cable company's decoder, whether your local system uses letter or number designators. Only cable TV channels 2 through 13 correspond directly with the off-air channel frequencies. From that point, CATV channels bound across the spectrum, borrowing slices of RF real estate along the way. Although it's not shown on this chart, in some systems frequencies as low as 5 MHz are used! (Source: *Scientific Atlanta*.)

FCC Rules Governing CATV Service

Part 76 of the FCC rules is on the mind of every CATV system operator. This section governs how he operates his CATV system, and spells out the technical standards he must follow. The *FCC Bulletin* reproduced here in part (FOB Bulletin No. 17), is a checklist CATV operators can use to ensure compliance. Rules 76.601 and 76.611 are of particular interest (and help) to amateurs. Rules 76.613 and 76.614 apply in the special case of cable TV frequencies shared with aeronautical services. Keep in mind that some leakage is tolerated; you might hear leaks during your tone-sniffing survey that are entirely legal. How much radiation is tolerated? FCC rules state that, at 2m frequencies, a leaking CATV signal's strength cannot exceed 20 microvolts per meter at a distance of 10 feet. You'll probably have no way of knowing the actual field strength of any leaks you encounter. Note them all, anyway, following the guidelines given in the main article, for the benefit of the service technician. He'll be able to sort out the strong ones.

Reverse Psychology

In some areas, amateur repeaters at the low end of the 2m band have long suffered QRM from leaking CATV signals. The concepts described in this article work for tracking down these leaks and resolving them. Think of it this way: If leaking CATV signals are ruining 2m repeater operation, surely some ham in the area is getting into *their* system, too . . . Use a little reverse psychology to solve this one!

What to do if the Tracer is Off

Occasionally, lightning or equipment failure will knock a cable company's FM band tracer system out of service. If so, you'll have to resort to conducting your search with different equipment. Your 2m mobile rig and 2m HT, or a scanner, will fill the bill. (Be aware of your state's laws regarding scanners in automobiles, if you employ one for the search.) Although these methods won't be as inconspicuous as a Walkman or the FM receiver in your car, they will work. Instead of a tone, you'll be searching for the actual audio portion of a cable TV channel. Here's how: Refer to Table 1 for the audio sideband frequency of a CATV channel within the tuning range of your 2m rigs or scanner. I suggest channels A through E, as these lower frequencies carry farther once they've escaped the cable. After programming your rig, drive or walk the area listening for the audio portion of the TV channel you've targeted. Zero in on it in the same manner as described in the main article for the FM receiver. Use a scanner or your mobile 2m rig with an external antenna for the general search, and an HT for pinpointing leaks on foot.

What to do if the FM Tracer is Gone!

Depending on how progressive, or financially flush, your local cable company is, they may have upgraded their leak tracing system beyond the FM band leak tracer. The new generation of leak tracer uses specialized equipment which searches for actual video radiation on chan-

CATV Notes

nels A, B, or C. These are aeronautical frequencies, slightly above the FM band. Why the switch from a perfectly good system that was also easy for *us* to track? One incentive for the cable operator is that the new system frees FM band frequencies for commercial use. Cable systems sell an entertainment product, but no one would pay to hear a repetitive whooping tone! (Unless, of course, the customer happens to be a ham—the type who parks his receiver on WWV for hours on end . . .). If your cable system *has* made the switch, use the tracking methods described in "What to do if the Tracer is Off."

Portable TVs as Leak Detectors

It's tempting, but leave the portable TV at home; it won't work well as a CATV leak sniffer. The video component of a leaking signal weakens too quickly with distance. Beyond five feet or so of an egress, a consumer-grade TV will not detect a leak source. Also, note that only CATV channels 2 through 13 correspond directly with the frequencies of off-air TV, so it's difficult to tune the entire range of cable channels.

Neighbor PR

A little premeditated public relations effort with your neighbors goes a long way. Really now, why be hard-headed about it? Try a gentler approach. I always start with: "I'm *sorry* that I'm affecting your TV/radio/telephone . . ." It can be positively disarming, and that can work in your favor. Ditto with the cable company.

What to do when the Problem is Wrapped Up

When an RFI case of any type is finally wrapped up, I make a call to tie the ribbons on it with my neighbor. I do this to get his agreement that it is resolved, or (put the words in his mouth if necessary) "99% better, and acceptable."

Also, call the cable company and leave a message for your contact person to say thanks. Our CATV system manager went so far as to tell me to encourage other amateurs to contact him if they encountered similar problems. You can open the door for your brother and sister amateurs with this follow-up call.

Lastly, write down what you did and learned. Others can benefit from this knowledge! Share it with your local club, repeater group or packet organization.

High-Pass Filters . . . One Thing *Not* To Do

A local amateur, N8LDQ, also experienced serious CATVI shortly after my situation was resolved. Interestingly, he found that a high-pass filter, a typical TVI *solution*, was *causing* the cable system shield breach at a neighbor's home. It was a poorly-shielded L/C unit which let 2m energy in and cable energy out. Although it would have been a fine approach to an HF-related source of TVI in an off-air TVX case, in the cable system it was a Pandora's box (or gateway).

The Cable Company Field Tech and You

Try to meet the cable company technician who performs the investigation and repair work. There are two reasons to do this. First, if you impress him as a technically competent and helpful individual, you'll enhance the image of our hobby. This will help your case, and those who follow you. Secondly, you might *learn something!* (Then pass it on at your next ham club meeting!) Keep in mind the poor tech's lot: He enters the home of strangers, deals with their smoke and pets, must figure out and fix the problem, all while playing referee between the subscriber, his company and possibly even you! If you can ally the CATV company tech, your job of resolving the matter will be more effective, and quicker to succeed.

the Cumulative Leakage Index). It's not a good point to open the conversation on, but can be worked in during the visit.

Be prepared, also, for the possibility that your neighbors have not yet registered a complaint with the cable company, and you made it there first.

Once again: The basis of your position is that you are entering and QRMing the cable system because it has some type of shield integrity problem. Likewise, their signal is get-

ting out. You are licensed to transmit over the air on 2m; they are not! The problem is theirs, whether it's a subscriber's poorly-shielded jumper, or their own damaged cables. You've even helped them locate it! Both economics (lost revenue due to mad subscribers) and the FCC inspire them to return their system to a shielded, leak-free condition. Remind them of this, ever so politely. Always end with a polite "thank you," noting you are willing to assist.

Now, reread the last paragraph, pump yourself up, and go! In the unlikely event your contact attempts are rebuffed, a letter to the system manager is the next recourse. Keep copies for reference. You might need them later on. That's it, the third and final step!

In the Meantime

At all times you should be making an effort toward good public relations. If you favorably impress your neighbors with your efforts, and maybe even self-impose some quiet hours until the problem is cleared up, they'll have a better impression of you and of our hobby. (Also, in the future they might overlook the fact that your kW on 40m makes their phone chirp a bit. You can reap the benefits of this PR effort down the road, too!) You should tell your neighbors you are working with the cable company to resolve the problem. Explain as much as they want to know. Keep relations good, and try to enlist their help in your troubleshooting efforts. Besides being the right thing to do, allying yourself with your neighbors is the most prudent path to follow. You may even need their assistance at some point to pressure the

CATV company to resolve the matter.

If, after all this (and only as a last measure), no positive results are attained, write your FCC Field Office. Addresses are in the ARRL's *FCC Rule Book*. This is a last resort, though. My philosophy is that if you present yourself in a friendly, positive, and reasonable manner, you'll receive excellent response from your cable company. More often than not they will be ready to resolve the problem and will welcome your assistance. Case in point: My local cable company took less than 24 hours to solve my CATV problem once I brought it to their attention.

I also recommend you obtain a back issue of *QST*, October 1990. On page 42, two Cable TV employees, who also happen to be hams, offer some insight in the "Hints and Kinks" column. Your library can probably obtain a copy of that page through interlibrary loan, depending on their copyright agreement. Another reference well worth obtaining for your shack library is the *Interference Handbook* by William Nelson WA6FQG. It treats a wide range of interference subjects, including that of CATV, in depth.

It's late, and time for me to sign off. I'll leave you with these final thoughts: You want this resolved, and you don't want your neighbors ticked at you. They probably blame you, even though it's likely that the problem is the cable system's shortcoming, or even their own fault! Keep their viewpoint in mind though: Everything was fine until "that ham down the street" went on the air. So do things right, be helpful; but remember—you are licensed to use the airwaves. Persist!

Part 76—Cable Television

Rule/Reference Suggested Procedure

Leakage Tests

Rule: 76.601 Conduct leakage tests once a year to show compliance with leakage standards in Rules Section 76.605. Maintain complete test data from annual tests for 5 years.
Note: Performing regular monitoring and leakage repairs in accordance with Section 76.614 will ensure that your system complies with leakage standards.

Cable Television Basic Signal Leakage Performance

Rule: 76.611 Conduct a test once a year to establish conformance with the Cumulative Leakage Index.

Interference from a Cable Television System

Rule: 76.613 Stop operation immediately and correct any condition that threatens radio navigation or other safety-of-life services.
Before reactivation, submit an interference report to the Field Operations Bureau of the Federal Communications Commission. Await response from Engineer in Charge before resuming operation.

Regular Monitoring

Rule: 76.614 Provide for a program of regular monitoring for signal leakage by checking the entire plant every 3 months when using aeronautical frequencies. Maintain a log of leakage sources, probable causes, and corrective action taken for 2 years.

by Dave Martin W6KOW

The HANDI-Finder

Build this versatile, accurate DFer semi kit in an evening.

North Olmstead Amateur Radio Depot
(NOARD, Inc.)
29462 Lorain Rd.
N. Olmstead OH 44070
Telephone: (216) 777-9460
Price Class, partial kit: \$27.95

Reasons for owning radio direction-finding equipment are many. DF gear can be used for locating a source of unintentional interference, documenting jamming, or for what is probably the best justification of all: The fun of T-hunting with a local group of transmitter hiders and hunters.

To get beyond the hand-held-next-to-the-body method of determining the bearing to a transmitter, some specialized gear is needed. Even at VHF and UHF, often-cumbersome DF antenna arrays are often seen connected to exotic equipment carried by serious DFers. By contrast, the HANDI-Finder DF device marketed in partial kit form by North Olmstead Amateur Radio Supply Depot is small enough to be hand-held, is easy to use, provides a sharply defined bearing, and is inexpensive. Its only apparent disadvantage is 180-degree ambiguity; if you don't know the general direction of the signal, you will have to move until the bearing changes to solve the problem of whether you are receiving the "front" or "back" of the signal.

Designed by Bob Leskovec K8DTS and based on a circuit published for use by the Coast Guard Auxiliary, the HANDI-Finder be-

comes the antenna for an ordinary hand-held radio on either FM or AM. A carrier is needed to make the system work. The HANDI-Finder works by switching at an audio rate between two antennas. In addition to hearing the signal's modulation, the operator hears a constant audio tone—until the plane of the two

"Getting into the open, however, demonstrated that the HANDI-Finder works as advertised."

antennas is perpendicular to the signal path. The tone then nulls sharply, indicating the bearing to the target transmitter, which is 90 degrees to the antenna plane. Modulation on the carrier is unaffected; only the tone nulls.

How It Works

Powered by a 9 volt radio battery, the circuit is based on a single CD4047B IC that

contains an oscillator and a flip-flop that provides complementary symmetrical square-wave outputs. Switched at an audio rate between two antennas, the switching-rate audio tone is heard unless both antennas are receiving the signal at the same time and are therefore in phase.

Building It

The North Olmstead kit includes a 1-5/8" x 6" circuit board with all of the electronic components mounted on the board. Working carefully, I finished the circuit board in 45 minutes. Not included in the kit are the antenna elements, coax and connector, handle, battery, and two 1/8" pop rivets to mount the battery holder.

For antenna elements, I used two 18" lengths of 3/32" brass welding rod. (My nearby welding supply store simply gave me two rods—enough for two sets of antennas—rather than writing up such a small order.) The vertical parts of the antennas are the receiving elements, and the distance between them can be optimized for a particular frequency band. For DF work mostly on 2 meters, I settled for a spacing of about 14 inches. After forming the U-shape elements, I soldered crimp-type wire connectors that are bolted to the circuit board.

The 13-page construction and operations manual suggests using a paint-roller handle to hold the HANDI-Finder. I chose a \$1.42 plastic model that is threaded at the bottom and fits a painter's extension pole. A vise and hacksaw came in handy. Attaching a 6-foot length of 50 ohm coax and a BNC connector completed the building project.

Using the HANDI-Finder

First experiments were near my house—too near, as it turned out. The manual notes that used indoors, too close to buildings or even large trees, multipath signals will provide multiple nulls and no clear indication of bearing. Early experience confirmed this.

Getting into the open, however, demonstrated that the HANDI-Finder works as advertised. The audio tone is apparent even on weak signals, and there's a sharp null when the antenna array is perpendicular to the bearing to the transmitter.

The final test was to talk my wife into driv-

Photo A. The HANDI-Finder kit was easy to assemble in less than an hour.

Photo B. The compact, lightweight unit is powered by a 9V battery and mounted on a paint-roller handle.

ing around as I simulated a T-hunt with the HANDI-Finder on its paint pole outside the car. I cheated by knowing approximately where the transmitter was—the continuously-broadcast, low-power ATIS (automatic terminal information service) AM signal associated with the control tower at an airport about six miles from my house. This target was picked because I knew I could get quite close to the transmitter without driving to the top of a mountain.

We played the game. First we solved the ambiguity problem by driving far enough to get a consistent bearing shift. I found that "picket fencing" associated with weak signals heard while underway mobile prevented getting a distinct null; we pulled to the curb a lot. Within 20 minutes, though, we were close to the airport, and driving around it confirmed that the ATIS antenna is on top of the control tower.

The Bottom Line

The HANDI-Finder works well on any carrier-based signal that its IC can hear. By changing the antenna elements, the unit should work as low as 50 MHz and as high as 450 MHz. The circuit could also be used with a pair of directional antennas that would solve the ambiguity problem from one location—at the expense of hand-held portability.

In its simplest form, using a hand-held radio with a HANDI-Finder offers versatile, accurate, easy-to-use direction finding for about \$35. How could you beat that?

"BRONX BOMBER BERNIE"

...presents the best way for NEW HAMPS to upgrade your skills. If CW is frustrating, here's the decoder/tutor for you.

All hams, and SWL listeners, too, will enjoy years of visual decoding.

"In my 50 years in radio, this is the best decoder and tutor I've seen. Morse (CW), RTTY, AMTOR, SITOR, NAVTEX...all spelled out on a bright LED read-out. It's great for viewing what you're transmitting, too!" says Bernie, the B-17 radioman and long-time ham expert. High quality, English construction.

- Touch-button control / 7 function keys
- DPS Filtering aids decoding
- Built-in RS232 port for PC and printer operation
- 12v to 16v DC

A NO-RADIAL VERTICAL THAT COVERS 80 OR 75 METERS?

THERE'S ONE NOW!

No, we won't insult your intelligence by telling you that it's a "halfwave" or that ANY vertical will operate more efficiently without a good radial system than with one; it certainly won't! If you want expensive fairy tales talk to our competitors! If, however, you've no room for even the smallest radial system just install the most efficient multiband vertical in the business, the HF9V-X, over our counterpoise kit. You'll not only save a tidy sum but you'll work DX that the shorter and more lossy no-radial "halfwaves" can't touch because both the HF6V-X and HF9V-X use longer active element lengths for higher radiation resistance and greater efficiency on more bands than any of the so-called halfwaves. Ask for our free brochure for complete specs on all Butternut models and receive technical note DLS-1 "Dirty Little Secrets from the Antenna Designer's Notebook" that shows you how to calculate the probable efficiency of any vertical antenna using the manufacturer's own specs so you won't have to learn the truth the hard way!

NEW!

Model HF9V-X (shown to the left) for 80/75, 40, 30, 20, 17, 15, 12, 10 and 6 meters.

NEW!

Model CPX counterpoise kit for Butternut models HF9V-X, HF6V, and HF6V-X; substitutes for ground or elevated radials. Self-supporting tubing bolts onto base of antenna. Mast not provided.

BUTTERNUT ELECTRONICS CO.

Five-Element T-Match VHF Yagi

Excellent performance characteristics on 2 meters.

by Marty Gammel KAØNAN

I finally decided to get started on a long-overdue new yagi for my rooftop antenna farm, here in Minnesota. I needed a clean pattern with about 9 to 10 dB gain for FM repeater and simplex work.

I have tried several different types of antennas in the past, but I've never tried using the "T" match with a half-wave balun. So, I looked in the *ARRL Antenna Book*, 15th edition, for guidance. The balun looked easy.

Due to our harsh winters, I needed to enclose the balun, and I also needed a good solid mount for the "T" match feed point. I chose a plastic box from Radio Shack that measured 2-1/2" by 4-5/8" to house the balun. The beam itself was easy, using a 5'-long square boom from an old TV antenna as a starting point. After removing the old elements, I decided to use a close standard spacing of 13" for reflector-to-driven-element spacing. I wanted a close-spaced first

director, so I used 9" for driven-element-to-first-director spacing. For second and third directors, I used 15-1/2" and 17" spacing. The 1"-square boom was big enough for this small, 5'-long antenna. I used 3/8" diameter aluminum tubing for all the elements and the "T" match bars.

As an extra feature on this antenna, also from the *ARRL Antenna Book*, 15th edition, I added a ferrite bead choke on the quarter-wave line section of the balun. The local electronic surplus house proved to be a source for cheap ferrite beads. I also

Photo A. Balun assembly, ready to install.

wound the half-wave section of coax into a four-turn choke to fit into the plastic box. The combination of the ferrite beads and the four-turn choke gives good isolation of the feedline and avoids radiation from the feedline shield. The dimensions for the "T" bars came from standard design lengths for gamma match parts. The "T" match design gives a very clean design, without skewing.

Building the Beam

Once all the old elements have been removed from the boom, mark where you need to drill to mount all five elements. I found that by mounting the elements in the center of the boom, the spacing for the "T" bar straps was more manageable. The beam will also look better. If you can use a drill press to make the element holes, they will probably be more exactly perpendicular to the boom. After the holes are drilled, try

Figure 1. Five-element 2 meter beam.

fitting the 3/8" tubing in each hole and check for squareness to the boom with a square.

Cut all the elements to length, and flatten one end of each of the two 6-1/2" match bars—about 1/2" will do. Drill a 1/8" hole in the flattened area and round off the corners (see Figure 2). Attach all five elements to the boom using the 1" stainless steel screws.

Now drill holes for mounting the SO-239 and the 1" #8 bolts in the plastic box, and attach the SO-239 with three of the four bolts (see Photo B).

Assembling the Choke and Balun Assembly

Start with a piece of RG-59U about 14" long and prepare both ends as shown in Figure 2. Do the same to a 26-1/2" piece for the other balun section. Allow 3/4" on each end of both coax sections for dressing the ends. Wind the longer section of coax into a four-turn coil. Tape the coil temporarily in a couple of places, just to hold it until the finished balun is installed in the plastic box. Solder the shields from both sections of coax together (see Photo A). Install the balun assembly in the balun box; be certain all connections are correct. Install a closed-end crimp-type connector on each end of the center conductor of half-wave coax. Install the 1" #8 bolts through the crimped connectors using washers, and apply a washer and nut to the outside of the plastic box. After doing this, remove the tape from the coil. Install as many ferrite beads as you have room for on the end of the quarter-wave coax section; I had room for six ferrite beads. Solder a closed-end crimp-type connector to the shield and then connect it to the fourth mounting bolt for the SO-239 panel-mount fitting. Solder the center conductor to the center terminal of the SO-239.

Apply Crystal-Cote or some other type of sealer to everything in the balun box. Attach the "T" match bars to the balun box, and bend the ends of the metal strapping around the driven element and match bar. Then drill holes to bolt the straps to the tubing (see Photo B). You will need about 1-3/8" between the "T" bars and the driven element. Spacing for the strap should be about 4" from the center of each 1" #8 stainless steel bolt on the balun box. Fashion a mounting bracket to connect the SO-239 to the boom. It must be a metal bracket to provide the needed electrical connection between the boom and the balun. I used a piece of plumber's perforated strapping that was in my junk box, and cut it to shape with tinsnips. Mount the bracket to the boom with a sheet metal screw (see Photo B). Drill a weep hole in the lowest corner of the balun box for drainage once the box has been mounted on the boom.

Check all connections, nuts, bolts, and screws, and then mount the antenna on a non-conducting mast, ready for tuning. Tape the coax to the boom and bring the coax

Figure 2. Balun box for 2 meter yagi.

Photo B. Close-up of balun box. Note the "T" match bars and the driven element.

down the mast, away from the antenna.

Tuning the Completed Antenna

Tuning the antenna is easy. Connect the coax, SWR meter, and your radio to the antenna. Check the SWR at the top, center,

and bottom of the frequency area of design. By noting the pattern of the SWR curve you will know whether to move the match bars in or out for the best match. Move only about 1/8" at a time, rechecking the SWR curve as you go.

Mine was very close to the center of the designed-for frequency, and only had to be adjusted about 1/8" from the text. *Be sure to make all adjustments of the straps on the "T" bars equal.*

Builder's Notes

I bought the ferrite beads and the plastic box to make a clean weatherproof feed point, but all the aluminum came from my stockpile of old TV antenna parts. All hardware is common, and can be bought from any local hardware or building supply store.

"Be careful when you are cutting the coax to measure the lengths, and check the velocity factor for the coax you use."

I cut all the aluminum to length with a tubing cutter; this gives a more finished end than if you cut it with a hacksaw. Each element is installed through the center of the boom and fastened with a 1" #8 stainless steel screw (two screws are not needed for each element). Any type of non-metal spacer that you have may be used for supporting the balun box, to give the proper spacing for the "T" bar straps. I put a 1" sheet metal screw through the plastic box and spacer to hold them in place. If you cannot find an old TV boom, most local scrap metal dealers sell aluminum square and round tubing.

Be careful when you are cutting the coax to measure the lengths, and *check the velocity factor for the coax you use*. My RG-59U had a velocity factor of 66%. The number of ferrite beads is not critical, but they do stop radiation back down the coax shield. Be sure to drill or file the hole for the center of the SO-239 just big enough, but not so big that you get a sloppy fit—it does have to seal out the weather. Tune the antenna before you weatherproof and seal up the plastic balun box in case you may not have wired the connections right. Make

Photo C. Completed five-element vertical yagi.

Tools List

Electric drill
 3/8" drill bit (for holes in boom for elements)
 1/4" drill bit (for removing old elements from boom)
 3/32" drill bit (for #6 bolt holes for SO-239 mounting)
 5/32" drill bit (for #8 screw holes)
 Tinsnips
 Electrical tape
 Waterproof sealer (for balun; can be spray or brush-on)
 Plumbers' strapping or thin copper or aluminum (for balun, and "T" bar to driven element mounts)
 (Optional) drill press for drilling all holes
 (Optional) 9/16" drill bit for SO-239 to balun box center hole, or you can use a 1/2" drill bit and file as I did.
 Solder and soldering gun (for crimp type connectors inside balun)

nice neat pigtails on your coax ends so that they will be easier to attach. This design, with its close spacing, gives a very clean pattern of radiation, with at least 9 dB gain and a front-to-back ratio of 32 dB.

Many thanks to John Berglund KØUBA for his help in editing. If you have any questions, send them along, with an SASE, to me at 1703 Hewitt Ave West, St. Paul MN 55104-1128. 73 and happy hamming. 

Parts List

5'-long 1"-square aluminum boom (old TV antenna type)	6 #8 by 1" flathead self-tapping stainless steel screws (for elements)
2-1/2" by 4-5/8" plastic box (Radio Shack #270-222)	2 #8 by 1" flathead self-tapping stainless steel screws (for balun mounting)
3/4" by 1" spacer (wood, plastic, etc. for balun box mounting)	4 #6 by 3/8" flathead bolts with nuts & washers (for SO-239)
5 to 8 ferrite beads to make a ferrite choke (see text)	1 SO-239 panel mount fitting (for feedline attachment on balun box)
12.5" section of RG-59U coax (finished length) (see text)	2 1/2" by 3" metal straps (for attaching "T" match bars)
25" section of RG-59U coax (finished length) (see text)	4 #6 by 3/8" flathead stainless steel bolts with nuts & lock washers
2 pieces 3/8" by 6-1/2" aluminum tubing ("T" match bars)	3 crimp-type closed-end connectors (for coax connections inside balun)
1 piece 3/8" by 39-3/4" aluminum tubing (reflector element)	
1 piece 3/8" by 38-7/8" aluminum tubing (driven element)	
1 piece 3/8" by 37-7/8" aluminum tubing (first director)	
1 piece 3/8" by 36-3/4" aluminum tubing (second director)	
1 piece 3/8" by 35-1/2" aluminum tubing (third director)	
2 #8 by 1" flathead bolts for attaching "T" match bars to balun box	

You may have to find a few assorted bolts and washers in your junk box to complete this antenna (see text.)

Remote Tuned Active Antenna

Tune this easy amplified HF antenna without leaving your chair.

by Ken Cornell W2IMB

The March 1993 issue of *73 Amateur Radio Today* contained an article that I wrote covering an active antenna using a MOSFET. As described, it is a very broadband device. By adding a tuned input circuit, a desired frequency range coverage can be increased in sensitivity and selectivity. The problem arises as to how to tune the remote antenna from the radio shack.

The practical solution is to use a varactor, also called a tuning diode. A varactor acts as a capacitor with an adjustable value which can be changed by applying a variable positive bias voltage.

The antenna circuit is shown in Figure 1. The varactor (V) is placed across the tuned circuit (L1/C1) in series with a 0.1 μ F capacitor that acts as a voltage blocker and a bypass. The variable voltage is fed to the varactor via an RF choke.

Due to the basic design, the antenna is basically a monobander; however, the construction cost is minimal and two antennas can be fabricated from a 10' length of 1-1/2" white PVC pipe.

Varactors are not a common item found in every mail order catalog, but I have found two sources: Hosfelt Electronics, 2700 Sunset Blvd., Stuebenville OH 43592; and DC Electronics, P.O. Box 3203, Scottsdale AZ 85271. Hosfelt has a variety and I have used their Motorola type SMV16623M (catalog #MV1662/S) that comes in three matched units for \$1. DC Electronics offers a variety of sizes that include AM tuning diodes with capacity ranges at 450 pF. I have ordered some of these to try out.

The tuned circuit (L1/C1) and the varactor (V) have to be resonant through the desired amateur band. For 80 meters, I used a small 5/16" diameter by 1" long coil form and wound 50 turns of #28 enamel wire. C1 is a 5-to-6-mm 50 pF trimmer. Try 100 turns for 160 and 25 turns for 40 meters. I usually wind more turns than my target value as it is easier to remove turns than add them. A small slug tuned form would also help in zeroing in on the desired range.

I used a 1-1/4"-wide by 3-1/4"-long

piece of perf board for the circuit and mounted the parts on both sides to permit insertion in the PVC pipe. Pipe caps are used at both ends and the coax cable is fed through the bottom cap. The antenna is a piece of 1" diameter aluminum tubing 4-1/2' long. Assembly is the same as de-

scribed in my original article.

The receiver coupler is shown in Figure 2. The variable voltage output to the varactor is fed through a length of insulated hook-up wire that is taped to the coax cable. A 6-32 S.S. machine screw is mounted in the base pipe cap to accept same.

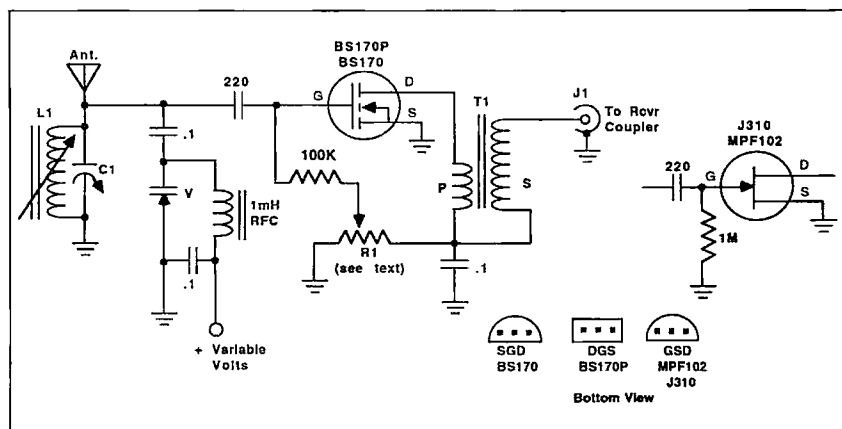

Figure 1. The remote tuned active antenna. Gate bias for the BS170 is most important for best performance. I used a 100k potentiometer for R1 and, after the proper setting was found, I measured the resistance each side of the potentiometer and replaced with same value 1/8 watt resistors.

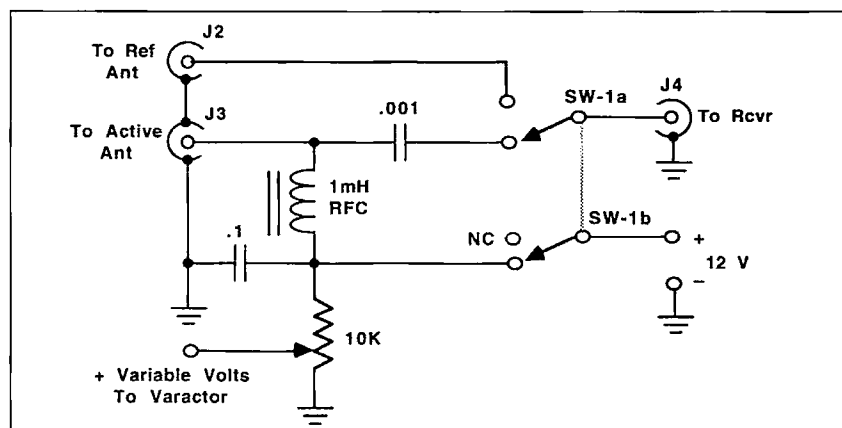

Figure 2. Receiver coupler: Except for the varactor tuning parts, all parts are as specified in my original article.

Figure 3. PC board pattern and parts placement diagram.

For the experimenter, a JFET can be substituted for the MOSFET. This minor circuit revision is shown in Figure 1a.

Parts List

- L1 To suit frequency range desired. I would suggest that you consider RF chokes for the inductance. They are cheap and come in many values to suit any frequency range desired. Consult your L/C vs. Frequency Chart (found in most handbooks).
- C1 50 pF trimmer capacitor. Used for frequency adjustment if needed.
- V Varactor. I suggest using VMAM109. It has a range of 450 pF @ 1 volt and 30 pF @ 9 volts (DC Electronics).
- Capacitors Are all disc type with 35 volt rating.
- Resistors All 1/4 or 1/8 watt carbon type.
- R1 100k potentiometer. RS #271-284 or equivalent. See text.
- R2 10k potentiometer. RS #271-1715 or equivalent. (Addition to the original receiver coupler design.)
- RFC 1 mH for HF and higher values for MF to LF. See text.
- T1 SPDT switch.
- SW1 Your favorite coax connectors.
- J1, J2
- BS170, BS170P Available from Digl-Key Corp., P.O. Box 677, Thief River Falls MN 56701; (800) 344-4539.

Drilled and etched PC boards are available from FAR Circuits, 18N640 Field Ct., Dundee IL 60118, for \$4.50 plus \$1.50 S & H.

2-1000 MHz In One Sweep!

AVCOM's New PSA-65A Portable Spectrum Analyzer

The newest in the line of rugged spectrum analyzers from AVCOM offers amazing performance for only \$2,855.

AVCOM's new PSA-65A is the first low cost general purpose portable spectrum analyzer that's loaded with features. It's small, accurate, battery operated, has a wide frequency coverage - a must for every technician's bench. Great for field use too.

The PSA-65A covers frequencies thru 1000 MHz in one sweep with a sensitivity greater than -90 dBm at narrow spans. The PSA-65A is ideally suited for 2-way radio, cellular, cable, LAN, surveillance, educational, production and R&D work. Options include frequency extenders to enable the PSA-65A to be used at SATCOM and higher frequencies, audio demod for monitoring, log periodic antennas, carrying case (AVSAC), and more.

For more information, write, FAX or phone.

Midland 73-005 Transceiver

A full-featured HT at an entry-level price.

Midland Consumer Communications Division
1690 North Topping
Kansas City MO 64120
Telephone: (800) 643-5263
Price Class: \$239

My first 2 meter rig was a digitally synthesized Heathkit mobile which utilized lever switches to change frequencies. It was a neat little unit that took me 40 hours to build and was a dream to use. Then one night, some low-life crumb decided to steal it, along with my '67 Plymouth Belvedere. Two days later the police recovered the car—stripped, of course. No tires, no wheels, no radio! That adventure kept me off the 2 meter band for a while. It also taught me one major advantage of using an HT as a mobile rig: You CAN take it with you when you go.

Sure, you sacrifice some output power and certain conveniences with an HT, versus a dedicated mobile. But, if you live or drive in the city, you'd better have some practical method of protecting your rig from theft. The only sure-fire method that I know of is to yank the rig! Consider the HT as a possible solution. An HT can sit on the seat next to you, keep you in voice with the local repeaters, and offer versatility that a mobile can't match. Simply remove the cigar lighter plug and the BNC coax connector, and you're good to go.

Of course, this illustrates only one of the many reasons why HTs have become so pervasive in recent years. If you're thinking about buying an HT, first you have to get past the Future Shock of what's out there. There are many to choose from! One way to narrow the field would be to ask: How much does a good 2 meter portable cost? Well, how much have you got?

Money is No Object

When I first laid eyes on Midland's latest venture into the amateur radio marketplace, I thought, "Hey! Not bad for a \$400-ish HT." I immediately delved into the liquid crystal display and buttons without ever checking into the price. (Herein lies the difference between purchasing and playing with a review unit.)

Well, I kept the test rig by my side for several weeks, happy as a clam, until I noticed the Model 73-005 in a catalog, sporting a \$239 price tag. What? Midland can offer this sophisticated, surface-mount technology, microcomputer-controlled, 2 meter transceiver for less than 250 bucks? (In case you haven't shopped around, this price falls into

the "rock-bottom" range.) So, how good could it be?

First Glances

Now, you're probably thinking, "Yeah, right. For that price it's probably a real no-feature cheapie." But the 73-005 HT is no slouch. This is a nice little radio!

The actual transceiver is a tiny 5-1/2" high by 2-1/8" wide by 1-5/16" deep. (I grew up pre-Nintendo, so I still find myself in awe over the cramming of so much electronics into such a small package.) Still, the Midland is somewhat larger than the very smallest rigs that I have seen. You can attribute much of that size to the big duckie and optional high-power battery. Even so, this unit has a clean look, and is quite small enough.

The LCD panel is easy to read, and it is flat. Many HTs on the market have convex panels that are susceptible to scratches. Midland's design avoids that problem.

Tough Enough

I like to carry an HT with me whenever I go mountain biking or hiking. They are very nice to have with you in the woods and in the mountains. You can stay in touch, listen around, or just know that you could summon help in the event of an emergency. One thing you don't need on the trail, however, is a fragile piece of gear.

The new Midland is solid. Very solid. The transceiver is constructed on a die-cast aluminum chassis. It resembles a commercial transceiver, which is no surprise, considering Midland specializes in commercial gear.

This radio is also equipped with a PTT LOCK feature. This deactivates the PTT button to prevent accidental transmitting.

Design

This baby is a tad more conservative in design than many of the latest HTs. It looks more like a police portable than some of those Star-Trek-looking amateur models I've seen lately. Still, I'll give Midland good marks for ergonomics.

The VOLUME and ROTARY CHANNEL SELECTOR controls are easy to adjust without looking at them. The push-buttons on the front pad were designed for daintier digits than mine, but I can still push them one at a time—even

with my sausage fingers. These buttons are of the rectangular rubber variety. They feel like the erasers of 16 tiny new pencils.

Say, where's the squelch knob on this thing? It was cleverly "sawed off" at the factory. The owner's manual describes this as a "set and forget" type knob, and I kinda like it. It reminds me of a child-proof cap on a medicine bottle. I don't like to constantly ride the squelch, anyway—it really isn't necessary. Still, if you're a knob twiddler, you may find this feature irritating. Tough twiddling on the Midland.

On the left side of the 73-005 you will find the usual-looking rubber-covered PTT button. Just above it is the FUNCTION button, which combines with the front panel buttons to offer a wide array of features. Below the PTT is a LOCK button which mechanically holds the battery onto the transceiver.

EXTERNAL SPEAKER and MICROPHONE jacks are located on the unit's top side, next to the BNC ANTENNA jack. In between the VOLUME and CHANNEL knobs is a little red LED. This indicator lights when the unit is transmitting. The light becomes dim as the battery weakens, indicating a charge is needed.

On the right side all you will find are a carry strap loop and an EXTERNAL POWER connector. This connector, like the MICROPHONE and SPEAKER jacks up top, has a little rubber plug to help keep water and dirt from entering.

There are two more buttons on the front of the 73-005 you need to know about (aside from the touch pad, of course): the CALL and the SQUELCH/MONITOR buttons. The CALL button will generate a 1750 Hz repeater access code when depressed along with the PTT button. This BURST TONE ENCODER is unusual on rigs manufactured for the U.S. market. The 1750 Hz tone is common in Europe, but rarely used in the States. The SQUELCH/MONITOR button simply shuts the squelch circuit off while it is depressed. Push it to hear weak signals that are barely breaking through.

The LCD display indicates frequency, channel step, and special functions. These include PAG (Paging), DUAL (Dual Watch receive), APO (Automatic Power Off), DUP (semi-Duplex operation), F.L. (Frequency Lock), T.SQ (Tone Squelch), P.L. (PTT Lock protection), C.SQ (DTMF Code Squelch), S (battery Save), B (Busy scan—rather than the pause scan default mode), and + and - (repeater offsets). The LCD also displays the memory address number and memory mode. The number line style meter across the bottom functions as an S-meter on receive, and as the RF power meter on transmit.

Special Attractions

The Midland 73-005 has more functions than you can shake a stick at. Let's take a look at some of the highlights:

- Large Capacity Nickel Cadmium Battery Pack
- LCD Control Panel
- Multi-Function Scan
- 20 Memory Channels
- Repeater Offset and Reverse Switches
- Tone Squelch + (P/L)
- Dial Lamp (LCD)
- Battery Save Function/Auto Power Off
- Instant Squelch Defeat/Monitor
- Speaker/Mike and 12 Volt Input Jacks

"Probably this rig's best feature is its hot receiver section."

Note: The Tone Squelch Module is an accessory, as is the oversized (high-power) 12 volt battery pack. A 12 volt wall charger and a speaker/mike are also available.

The 73-005 comes standard with some nice features. The DTMF (Dual-Tone Multi-Frequency) encode touch pad has become a staple in the market. But not all HTs have the decode feature as well, which allows you to emulate a personal pager of sorts. The LCD screen displays the number being decoded and "beeps" when activated.

Probably this rig's best feature is its hot

receiver section. The receiver is up to (low-end) commercial specs. 60 dB adjacent channel rejection is better than most. It is a highly selective radio with a very respectable 0.16 μ V (12 dB SINAD) sensitivity as well.

The receiver has extended range capabilities. You can dial up some local police and other agencies for the heck of it. You can also hear the National Weather Service. The VCO stays locked from 135 to 170 MHz.

The transmitter will put out 5 watts with an automotive 13.8 VDC power input. The Midland is not real picky about DC power; it will run happily on anything from 5 to 15 VDC. The circuit is reverse-polarity protected.

Note that the center pin of the 12 volt input jack is negative.

The transmitter section gives you plenty of choices when it comes to output power level. The B/PT.L button selects HIGH, MIDDLE, or LOW power operation. With the optional 12 volt battery, this will give you a choice of 5, 2.5, or 0.35 watts output. With the standard 7.2 volt battery you can select from either 2 watts out on HIGH or MIDDLE or 0.35 watts out on LOW power.

Semi-duplex operation is available by using two different memory frequencies. The 2/DUP button along with the FUNCTION button will get you into DUPlex mode. You can also swap the transmit and receive frequencies by pushing the C/SC/M along with the FUNCTION button.

You can select a frequency with either the ROTARY CHANNEL SELECTOR, or by direct entry to the keypad. You can adjust the channel steps with the 3/STEP and FUNCTION buttons along with the ROTARY CHANNEL SELECTOR knob. For repeater use, press the 7/SB button along with the Function button to switch from - offset to + offset to simplex operation. The offset is adjustable, too.

The Battery-Save function gives you even more choices. This function allows you to reduce the current drain to 1/3 during receiver standby. In this mode the receiver takes a sample once every single second. This is great for working voice out in the field, but it can be a problem receiving packet. Pressing the 5/SAVE button while pressing the FUNCTION button (located just above the PTT) toggles this feature on and off. The unit also has an Auto-Power Off function.

Midland shipped an accessory tone squelch board with the review unit. The Tone Squelch control allows you to gate a signal through the receiver squelch only when a particular CTCSS (Continuous Tone Controlled Squelch System) tone is being received. On transmit, you can similarly generate this particular subaudible tone to ac-

Specifications

Frequency Range	144-148 MHz TX, 130-170 MHz RX
PLL Lock Range	130-170 MHz
Modulation Type	F3
Channel Steps	5, 10, 12.5, 20, 25, 50 kHz
Antenna Impedance	50 ohm, unbalanced
Input Voltage Range	5.0-16.0 VDC
Nominal Voltage	7.2 VDC
Current Drain (approximate):	
Transmit	13.8V
	Hi 950 mA (5W)
	Mid 650 mA (2.5W)
	Low 350 mA (0.35W)
	7.2 V
	Hi 650 mA (2W)
	Mid 650 mA (2W)
	Low 350 mA (0.35W)
	Standby 0.35 mA
	Save 0.15 mA
	Auto pwr off 0.7 mA
RX	(144-148 MHz ham band only)
Sensitivity	(12dB SINAD) less than 0.16 μ V
20 dB quieting	Less than 0.25 μ V
Distortion	Less than 5%
Squelch sensitivity	0.16 μ V max
Audio output power 250 mW	10 % distortion at 8 ohms
TX	
RF output power	5W (13.8V) max
	2W (7.2V)
Max deviation	+/- 5 kHz
Freq stability	+/- 10 ppm from -20° C to +60° C
Spurious & harmonic emissions	Less than -60 dB
Dimensions	152 x 63 x 34 mm
Net weight	300 g (with battery and antenna)

Continued on page 37

Midland 73-005

Continued from page 35

cess "closed" repeaters or particular individual stations.

This miniature board took me all of 10 minutes to install, and five of those were spent looking for a small screwdriver. The clamshell housing comes apart lickety-split after removing just four screws. Inside there is a very neat array of microcircuitry. The thumbnail PC board sticks to the main board with its own adhesive backing and a tiny multi-pin plug makes all the connections. To operate the TONE SQUELCH feature, press the 4/T.SQ button while pressing the FUNCTION button. If you want to real get tricky, you can simultaneously utilize both the sub-audible TONE SQUELCH and DTMF CODE SQUELCH. Two independent subaudible tone frequencies

can be programmed into the memory banks. Tone frequencies are selected via the ROTARY CHANNEL SELECTOR.

Conclusions

For this review, I shoved the Midland 73-005 unit into my backpack, tossed it onto the passenger seat of my car, and clipped it to the handlebar bag on my mountain bike. It's been on hikes in the mountains, to the beach, everywhere. Let's cut to the chase. Money is important to most of us and this rig is priced quite reasonably. It offers more features than you will probably need. The receiver is hot and the rig is very sturdy. You can lock the PTT button and the operating mode to prevent improper operation. That's handy if you're active outdoors.

The speaker audio is very good. To get better audio you will probably have to fork

over quite a bit more money. I found this to be a cool radio, too. I didn't have a problem with the output power circuitry turning into a hot hamburger during normal use. (I don't usually rag-chew on 2 meters.) The aluminum chassis does a good job dissipating heat.

This is not the easiest HT to program. This article should give you a good feel of the essential operating hieroglyphics. Still, the Midland will perform well for you—just don't forget to bring the instructions along. The manual is detailed with plenty of illustrations to get you through.

Midland has made a triumphant return to the amateur radio business after a long hiatus. They have done a fine job with the 73-005 hand-held transceiver. Their next project is a UHF model, which is already in the works.

Melt Your Way to Better Breadboards

Discover the Macro Surface-Mount breadboard method.

by Brad Thompson N1JJJ

Chances are, you build one or more breadboard versions of your amateur radio projects before you commit them to a printed-circuit board layout, or you may even skip the PC version altogether and simply package the breadboard.

But if the fun's wearing thin and you're "bread-bored," your standard construction method may be at fault—no single breadboarding method meets everyone's needs. For example, perforated grid board and wire-wrap techniques work well for logic and low-frequency analog circuits, but lack an adequate ground plane for RF applications.

Isolated pads carved into sheets of etched copper-clad laminate solve the RF ground plane problem but are totally immovable, as are through-hole Teflon stand-off insulators. Terminal strips soldered onto copper-clad solve the relocatability problem, but they're relatively bulky and add to board height.

Enter the Macro Surface-Mount breadboard method, or MSM for short. Using the MSM technique, you keep your breadboard's copper-clad ground plane intact and install connection pads wherever they're needed. You can easily remove unwanted pads and relocate their replacements and, as Photo A shows, you can even build breadboards on almost *any* substrate—from window glass to business cards.

Best of all, you won't tie up much "bread" in your breadboards—the raw materials cost a penny or two per connection, and the tools you'll need are available nearly everywhere.

What are the secret ingredients? The connection pads consist of disks of thin single-sided copper-clad printed circuit board laminate punched from sheet stock with a \$3 hand-held paper punch (see Photo B). Hardware-store hot-melt adhesive secures the pads to the ground plane.

Forming the Pads

Printed-circuit board material consists of one or two layers of copper foil laminated onto an insulating sheet. While most of us are familiar with the thicker sizes sold for fabricating one- or two-sided etched circuit boards, the PC board industry also uses millions of square yards of thinner stock to

manufacture the inner layers of multilayer boards.

For MSM breadboard applications, you can use single-sided epoxy/Fiberglass board (commonly designated as G-10 or FR-4 stock). Material of 0.012" insulation thickness laminated with 1-ounce (0.0014") copper works well—a common hand-held paper punch easily penetrates the laminate, and normal levels of soldering-iron heat won't delaminate the copper.

To create MSM connection pads, you slide a piece of laminate into your paper punch and squeeze. The pad will pop out like a miniature tidilywink unless you place a finger over the punch's exit side.

If the remaining laminate sticks to the punch, work it free with a twisting motion. To prevent cuts while handling the sharp-edged laminate, wear a pair of lightweight cotton gloves.

No one will ever mistake a paper punch for a precision tool, and the fit between

punch and die is typically rather sloppy. Thus, squeezing the punch forms a raised lip or burr on an MSM pad's copper surface. If you punch through the board's insulated side (i.e., with the insulation in contact with the steel punch and the copper side against the punch's die) the copper burr overhangs the pad's edges and reduces the insulation path.

Also, epoxy/Fiberglass material acts as an abrasive, further wearing the punch. When the edges of pads exhibit a torn rather than sheared appearance, discard the punch or relegate it to paper and cardboard.

MSM's Electrical Properties

While epoxy/Fiberglass laminate and hot-melt glues offer dielectric strength of approximately 500 volts and 650 to 1300 volts per mil of thickness respectively (i.e. a 12-mil board should withstand 6,000 volts), the practical working voltage for an MSM pad cemented to a ground plane falls well below the dielectric limit.

Photo A. Using MSM techniques, you can build circuitry onto almost any surface from plate glass to business cards to wood to Plexiglas.

In practice, the creepage path across an MSM pad's edge from copper to ground plane determines the voltage flashover margin. While a ring of hot-melt glue around and beneath a pad may raise flashover voltage, glue thickness and thus flashover voltage is hard to control.

As a guideline, printed-circuit board design rules impose a 150 volt limit for trace-to-trace clearances of 0.025". Thus, adopting a maximum working voltage limit of 50 volts for a 12-mil (0.012") MSM pad-to-ground plane separation will provide a conservative safety margin. Of course, if you're using an insulating substrate, pad-to-pad flashover and substrate breakdown voltage limits will apply.

Pad area and dielectric layer thickness value determine the capacitance of an MSM pad mounted over a ground plane. For a worst-case assumption of no glue layer, calculated capacitance of a 1/4" diameter copper pad and 12-mil epoxy/Fiberglass dielectric layer is 1.06 pF (picofarads).

In practice, edge effects increase and the thickness of a hot-melt glue layer decreases capacitance. A cluster of four MSM pads measured 1.08 pF per pad, a value reasonably close to the theoretical capacitance.

Dissipation factor (DF), a measure of a capacitor's AC power loss, varies from 0.001 to 0.120 for hot-melt adhesives, a range that brackets G-10 and FR-4 laminates' DF of 0.018—given the small amount of adhesive used, RF losses won't present a problem in most MSM breadboards.

Applying the Glue

Use a sharp hobby knife or single-edged razor blade to shave a 1/8" by 1/8" by 1/16" thick flake from a hot-melt glue stick. Size and thickness of the flake isn't critical, but too little glue won't fully wet a pad's underside and too much glue will form a messy-looking ring around the pad. A little practice will demonstrate the proper amount of glue to use.

Place the glue flake on the substrate using tweezers or needle-nosed pliers. Put an MSM connection pad (copper side up) over or against the flake. Using a small (20 watt) soldering iron, tin the pad's surface with 60/40 rosin-core solder.

As the solder melts, so does the glue, which secures the MSM pad to its substrate after cooling. While the glue remains liquefied, you can slide the pad to a slightly different location. If you incorrectly place a pad, simply reheat and remove the pad. Use a section of copper braid or solder wick to absorb leftover glue.

You can obtain MSM materials and tools locally, with the possible exception of thin-substrate copper-clad PC laminate. If your local surplus outlet doesn't stock the laminate, check mail-order surplus dealers who advertise in 73.

Also, contact local printed-circuit board manufacturers and PC laminate suppliers for availability of scrap and leftover material. To get started, you can purchase a 3" by 5"

trial sample, enough for over 200 MSM pads, from the author for \$4 postpaid (see address at end of story).

Assembly Techniques

BEFORE soldering a component to a pad, trim and tin all of the component's leads. Bend a lead to form a "foot" and place the "foot" on the pad. Apply a soldering iron to the lead and pad, simultaneously melting the solder and softening the glue. Adjust the pad's position, if necessary, and remove the iron. Allow the glue to cool for approximately 30 seconds before moving the part or bending its leads.

As noted, MSM pads can slide on a "bearing" of molten glue, but the first component lead soldered to the pad effectively pins the pad in place. While the first connection is the most difficult to make, subsequent connections go more easily.

Use a hemostat or locking tweezers to hold a component while soldering. Grasping the lead between component and connection helps keep excess soldering heat out of temperature-sensitive components.

For best results, use a low-wattage soldering iron—a 20 watt iron with a 1/16" tip works well. To solder leads to a copper-clad ground plane, use a larger iron of 40 to 50 watts capacity. Apply enough heat to make quick, clean connections and minimize softening of the glue securing adjacent component pads.

If you're installing MSM pads over a ground plane, use an ohmmeter to check for pad-to-ground short circuits caused by excess solder or too-long component leads.

To make connections between pads, use light-gauge solid- or stranded-conductor wire. Solid wires hold their shape when bent, an advantage when routing many conductors among pads. You can use thermally-strippable magnet wire for interconnections, but for best results trim and tin individual wires before soldering to pads. Tinned copper wire strung with sections of insulating tubing also works well.

Layout Suggestions

While the MSM method encourages a free-form approach to breadboarding, you'll get best results by planning your layout before you place a single pad. Proceeding from input to output, convert your schematic to a component-placement diagram. Allow a 1/4" circle for each MSM pad at a connection point. If you're using a copper-clad ground plane, allow a margin of approximately 1/4" to 1/2" around the ground plane's edge for mounting holes and a shielding box, if required.

Route power busses parallel with the sub-

Photo B. A tight-shot of the MSM connection pads.

strate's edges. In general, you'll find that MSM layouts can closely follow a circuit's schematic diagram, easing troubleshooting and modification.

Given a copper-clad ground plane, there's no excuse for insufficient RF filtering. You can liberally sprinkle bypass capacitors from MSM pads and power-distribution points to ground. When bypassed on either side, a low-value resistor passed through a clearance hole in a shielding partition serves as a feedthrough insulator.

You can use DIP (Dual-In-Line Package) components in a predominantly analog- and discrete-component MSM layout via "dead-bug" and "porch" techniques. In the dead-bug approach, you place the part with its pins in the air and bend power and ground pins to contact MSM pads and the ground plane respectively. Use individual pins as connection points for wiring—AWG #30 wirewrapping wire works well.

As an alternative, you can mount DIP components on sections of perforated board or salvaged printed-circuit board, wiring the ICs as a socketed subassembly and then securing the "porch" board to the ground plane with hot-melt adhesive. If your design consists mostly of DIP components, build the circuit on perfboard and tack on discrete parts via MSM pads.

If you experiment with nontraditional circuit substrates (e.g., cardboard or unused ashtrays), consider the substrate's mechanical and electrical properties. While an MSM pad and its glue provide a margin of insulation, wood, paper and cardboard lose mechanical strength and can become conductive when wet, causing electrical sneak paths.

Glass and plastic substrates offer superior insulation but require careful handling and mechanical mounting. In general, remove dirt, grease and corrosion products from surfaces before applying hot-melt glues. Otherwise, MSM pads may separate from the substrate due to poor glue bonding.

You can use a transparent plastic box with a removable lid as an enclosure for an MSM circuit by building the layout on the box's lid. However, the plastic may soften beneath each MSM pad, so apply minimum soldering heat for best results.

If you're uncertain about selecting a particular combination of substrate and hot-melt glue, conduct a pull test by attaching an MSM pad to the substrate and soldering a

1/4 watt resistor to the pad. Allow two minutes for the glue to bond. Secure the substrate in a vise.

Using pliers to grasp the resistor's unsoldered lead, apply a steady pull at a 45-degree angle with respect to the substrate. If the glue bond fails before the resistor fractures or the soldered connection peels, choose another glue or substrate.

When assembling an MSM breadboard, remember that bends in a component's leads help alleviate mechanical stress induced by soldering heat. Also, raising a component's body above the substrate improves heat dissipation and provides clearance for cross-under wiring.

Depending upon formulation, hot-melt glues soften at temperatures ranging from 70 to 163 degrees Celsius. Therefore, avoid designs that heat the substrate or dissipate large amounts of power into MSM pads via component leads. Provide longer component leads for extra cooling.

Assembly Ideas

As an alternative to a paper punch, you can use sheet-metal snips or even heavy-duty scissors to cut rectangular pads and bus strips. However, circular pads are free of sharp corners which can cause short circuits.

Lightweight copper-clad material forms easily-assembled shielding partitions and enclosures. Use EMI-suppression conductive adhesive-backed copper tape to form corners of shields and for seam coverage. For permanent tape-to-substrate bonds, tack-solder the tape and substrate at 1/4" intervals.

Hot-Melts for Hams

If your workshop includes an electric glue gun, chances are you're already familiar with the varieties and brands of hot-melt adhesives typically stocked by hardware stores. If not, here's a review of what's available.

Hot-melt glues come in three varieties. Polypropylene adhesives are yellowish white in color and slightly translucent. Ethylene vinyl acetate (EVA) glues are colorless and translucent. Polyamide glues are opaque and dark amber in color.

You'll find all three types in 1/2" or 1/4" diameter sticks of various lengths. You'll also find hot-melt sealants and caulking compounds—avoid these, as they don't adhere adequately for MSM applications.

In exploratory pull tests, all three types of hot-melt glues provided strong bonds—typically, components' bodies fractured before either solder or glue bonds ruptured. However, pads secured with white sealer/caulking compound failed during a moderate pull, well before component failure occurred.

Peel strength of copper on G-10 or FR-4 board stock is approximately eight pounds per inch of width. Various hot-melt adhesives offer peel strengths ranging from 13 to 45 pounds per inch of width, and thus an MSM pad's foil-to-Fiberglas

If you're modifying or repairing a conventional printed-circuit board, use MSM pads as tie points for discrete components. While it's preferable to secure MSM pads to an area of ground plane, in most cases you can also cover signal traces with pads. Trace-to-pad capacitance will amount to only a fraction of a picofarad per pad, and stray signal coupling shouldn't present problems.

Drawbacks to MSM technology include a tendency for reheated pads to slide on a glue "bearing." Use a scribe or soldering aid tool to hold a recalcitrant pad in place. Also, after repeated soldering and unsoldering, a pad's glue bond may weaken, forcing you to replace or reglue the pad.

Hardware built with MSM breadboards tends to spread in two directions, forming shallow layouts that are great for troubleshooting but somewhat hard to package for some applications.

While the author has used MSM technology for several months, MSM remains an experimental assembly method—long-term effects of storage, shock and vibration resistance, and repeated thermal cycling remain unexplored. In the tradition of amateur radio experimentation, the author releases MSM technology to the public domain. Your comments are invited.

NOTE: To obtain a 3" by 5" sample of 12-mil single-sided copper-clad laminate for experimental MSM pad fabrication, send a check or money order for \$4 (U.S.) postage and handling to: Brad Thompson N1JJJ, 100 Powdermill Rd., M/S BX-233, Acton MA 01720.

bond will fail before the actual glue bond between pad and ground plane fails.

A \$0.25 single glue stick yields hundreds or thousands of connections, and a carton of sticks probably represents a lifetime supply for most amateurs. However, hot-melt adhesives offer all kinds of interesting possibilities and chances are, you'll use more than you expect.

Beyond MSM assembly, hot-melt glues offer additional applications for amateur radio. For example, you can tack wires in place, secure heavy or bulky components to a substrate, and mount subassemblies in cabinets. However, hobbyist-grade glue guns typically provide poor control of glue flow and produce unwanted stray filaments of glue.

Use a clean soldering iron operating at reduced voltage via a variable-AC transformer to daub beads of melted glue stick where needed. Hot glue adheres to everything (fingers included) and can cause burns, so wear gloves and use caution when applying the glue. Periodically wipe the iron's tip on a damp sponge to remove overcooked glue residue.

When applying hot-melt glue to large metal objects, note that the metal acts as a heat sink and may weaken glue bonds. Warm the metal beforehand for best adhesion.

Maxi-Loop 80

Here's a tried-and-true indoor favorite you can build.

by Richard Q. Marris G2BZQ

Those of us who frequent the lower HF bands (80 and 160 meters) know that sometimes the signal we want can sink into the ambient noise and disappear. This applies to both amateurs and shortwave listeners. The noise in question appears to be an amalgam of a number of sources—some radiated, some atmospheric, and some man-made.

Many hams resort to the use of a multi-turn tuned loop antenna for reception. Unfortunately, many are then disappointed with the resulting lower signal strength. Still, the loop's directional properties can reduce some of the noise. So, a preamplifier is inevitably used between the loop and the receiver. This increases signal strength, but also amplifies the noise.

Such lower HF loops are usually capacitor-tuned multi-turn affairs, with a single coupling turn. The loop's wire turns are spaced close together or are even touching.

The loop receiving antenna has been with us since the first days of wireless. It is usually seen in the form of a small-space domestic antenna. It is also used for direction finding (DF), especially in ships fitted with earlier radio telegraphy equipment. I know, because I collect old wireless books and I often used physically small-size MF and lower HF direction finding loops dur-

ing WWII. Their performance was often impressive.

A review of the literature shook my poor old brain box, producing the realization that these older-type loops were mostly

"The loop receiving antenna has been with us since the first days of wireless."

very, very efficient, small in size, and very sensitive. They usually had their multi-turns spaced well apart. I also recall that during more recent experiments with multi-turn small-dimension transmitting loops, the problem called "proximity effect" had

been encountered, usually from the wire turns being too close together. The proximity effect may occur in cases where insulated turns are close-wound (e.g. one wire turn apart). As the turns are brought close to each other, the current density around the circumference of each conductor gets redistributed. The result is a loss in sensitivity or signal strength. For any reader who is interested, the proximity effect is analyzed more deeply in the *ARRL Antenna Book* (16th edition), and in other textbooks.

I decided to experiment to try and improve the loop's sensitivity (i.e. signal strength) and selectivity (to reduce the ambient noise level and other interference). The experiments compared various turn spacings and various methods of coupling to the receiver. For the initial experiments, a convenient suitable-size cardboard carton was used as a simple frame. A reel of PVC covered hook-up wire and a roll of masking

Figure 1. Maxi-Loop 80 antenna profile.

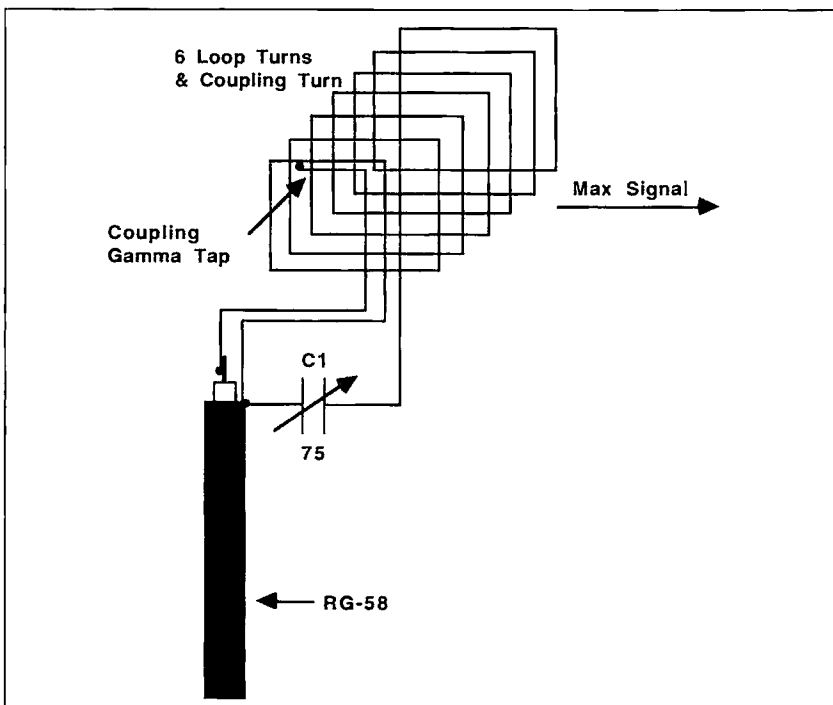

Figure 2. The antenna's electrical circuit.

Figure 3. The Maxi-Loop 80's frame and winding.

Figure 4. Mounting the antenna frame on the box.

tape held things in place and allowed for quick alterations. After several hours' work, using a frequency around 3.5 MHz, I wrote down a loop specification:

1. To be usable indoors, the loop must be small, lightweight, and decent to look at.

2. The goal is maximum sensitivity (i.e. greatest signal strength) with maximum selectivity.

3. A minimum of $1/8$ wavelength of wire would be necessary, as performance falls off when proceeding with much less.

4. The estimated size was $18" \times 18" \times 6"$ using six wire turns spaced at $0.6"$ apart, from conductor center to conductor center.

5. A form of gamma match coupling

would be used in preference to the usual loop coupling turn.

6. To obtain the absolute best results the loop would be an 80 meter band monobander.

Design Description

The resulting loop profile is shown in Figure 1. The loop frame is neatly pivoted on the flared base with a small plastic box, which encloses the resonating variable capacitor and sundry wiring.

The circuit, Figure 2, shows a six-turn loop resonated by a 75 pF variable capacitor. The coupling to the receiver is a form of "gamma" match which, in the original

cardboard carton experiments, was proved to provide better sensitivity than the more typical coupling turn. The frequency range is 3000-5000 kHz, with excellent sensitivity. Note: If C1 is replaced with a 200 pF variable capacitor, this will give a frequency range of 1750-5000 kHz, with performance falling off somewhat below 2500 kHz but still usable. A slow-motion drive would then be required with $C1 = 200$ pF.

The resulting performance, throughout the 80 meter (3.5 MHz) band was lively, with a high degree of signal strength and good selectivity reducing the ambient noise level substantially. A preamplifier was not necessary with a good superhet communi-

cations receiver, and this is with the loop on a table indoors alongside the operating position. However, it must be remembered that the results from such a loop may vary from location to location and operator to operator.

Construction

The lightweight box-style mainframe is shown in Figure 3. It consists of four obeche wood panels 18" x 6" x 1/16". (Obeche appears to be similar to balsa wood, but stronger.) Of course, 1/16" ply, or other wood, could be used, with an increase in weight.

The four panels 18" x 6" are corner-glued together, with 1/4" x 1/4" molded wood corner bracers, as shown in Figure 3. Two 9" x 1/4" x 1/4" mounting/bracing strips are glued at the bottom, as shown in Figure 3.

Onto the frame wind six counter-clockwise turns of PVC-covered single-conductor 0.6 mm-diameter hookup wire, with the turns spaced at 0.6" apart from conductor center to conductor center. The same wire is used for the gamma match coupling turn, which is tapped onto the main winding 4" from the top left-hand corner (Figure 3) of the first turn. It is run alongside the first loop turn and touching it as shown in the circuit. The turn's ends (about 3") are secured by running them through small holes drilled in the 9" x 1/4" x 1/4" bracing/mounting strips, and they can be pruned back later during wiring. To keep the turns exactly 0.6" apart, a blob of glue should be placed on them at the frame corners. Note: After initial tests, the loop frame (and turns) should be varnished outside and inside with polyurethane varnish. This makes the somewhat flimsy loop frame/winding (Figure 3) quite rigid.

Figure 4 shows the plastic box (5-1/16" x 2-5/8" x 1-5/8"), which has a thin metal lid fastened with four corner screws into brass threaded corner inserts. The metal lid is not used.

First, C1 is mounted in the box end center, as shown, and the mainframe loop is secured to the box with two screws with washers and nuts (Figure 4). The two screws pass through the 9" x 1/4" x 1/4" bracing strips, and the inverted plastic box.

Using the discarded metal box top as a drilling jig, drill four holes through the flared mounting base, which is a rigid, colored plastic picnic plate, which loses its original identity when inverted and screwed to the box.

The RG59 coaxial feedline to the receiver is brought through a hole in the side of the plastic box, as shown, and is 48" long. It is cleated to the inside of the box.

After completing the simple wiring in-

side the box, the inverted plastic plate is screwed to the box.

Testing and Operation

After plugging the coaxial feedline into the receiver, which is tuned to 3500 kHz, C1 is rotated to resonance. This is repeated at 3800 kHz (4000 kHz in the U.S.A. and some other countries). There should be a frequency overlap at either end of the 80 meter band. The prototype tuned from approximately 3000 to 5000 kHz.

Tuning to various stations over the 3.5 MHz band, you should find that there is very adequate signal strength, with excellent selectivity and low ambient noise. The directivity of the loop is the usual figure-

"It is absolutely essential that the loop is deactivated on transmit, otherwise the whole transmitted power will arrive at the receiver input, with quite devastating results."

eight polar diagram, with maximum signal off the ends, and minimum on the flat side of the loop. However, due to the coupling method employed, one lobe is larger than the other. Though the purist may shudder at this, it is an advantage as it reduces other unwanted stations' interference on the reciprocal bearing (i.e. 180 degrees), and is a quite deliberate feature of the design. I haven't needed a preamplifier as there is quite adequate signal strength with the loop indoors at this location in a built-up area. The loop should be kept well clear of the room walls and metal objects and wiring and pipes, etc.

Using a 2 watt QRP transmitter as an experiment, it was possible to load up the loop. However, with those thin loop wire conductor turns, it is unlikely that the transmitted results would be very acceptable.

Though the construction is very simple, it must be followed as closely as possible as the design has been targeted at the 80 meter band only, and I've been somewhat amazed how critical the turn spacing appears to be to get maximum signal strength.

The transmitting amateur will obviously be using the loop with a receiver, and the main antenna on the transmitter. It is absolutely essential that *the loop is deactivated on transmit*, otherwise the whole transmitted power will arrive at the receiver input, with quite devastating results. The method that I adopted is to "short" the RG58 loop feedline at the point where it enters the receiver. This can be done with a manual switch, relay, or RF-operated device. Whatever the method adopted, it should be tried with great care at low power and then at gradually increased power. 

References

The following are some of the textbooks used for reference. The first two are readily available, whereas the others are collector's items. Such older textbooks should not be scorned, as the conclusion that I've reached is that some of the older loop designs were probably superior to many of the present-day designs. Such books can often be found at flea markets, etc.

Amateur Radio Via Satellites

Andy MacAllister WA5ZIB
14714 Knights Way Drive
Houston TX 77083

New Satellites in Orbit

A one-day delay due to poor weather conditions was the only snag in the launch of four new satellites carrying amateur radio payloads. Conditions for launch require that wind speeds not exceed 30 mph, horizontal visibility be at least 1,970 feet, and the cloud ceiling be 820 feet or higher.

On September 26, 1993, at 0145 UTC, the 59th rocket of the European consortium Arianspace lifted off from its South American launch pad carrying seven satellites bound for an 800-km-high polar orbit. The sidebar shows the sequence of events following engine ignition. While this launch was the 31st for an Ariane 4 booster, it was only the third time an Ariane 4 had been used without any strap-on boosters and the fourth time for the ASAP (Ariane Structure for Auxiliary Payloads) platform. The ASAP is a donut-shaped mounting plate for small satellites near the base of the main payload.

The Ariane 40 used for V-59 stands 180 feet tall with a lift-off mass of 240,000 kg. It is a three-stage vehicle capable of placing 4,670 pounds of payload into the desired polar orbit. The first stage (L220) is built by Aerospatiale, and is powered by four liquid-fueled Viking V engines. The second stage (L33) is built by MBB Erno, and is powered by a single Viking IV engine. The first and second stages use a biquid fuel. The third stage (H10) is built by Aerospatiale, and is powered by a cryogenic liquid hydrogen and oxygen fueled HM-7B engine.

Most Ariane launches are for communications satellites destined for geostationary orbits over the equator. The main payload on V-59 was SPOT-3, an earth observation satellite used for earth imaging and mapping. Its mass is almost 10 times that of all the other satellites on the mission.

Of the six small satellites launched, two were based on the microsat design from AMSAT-NA, four were of SSTL (Surrey Satellite Technology Ltd.) design, and one, *Stella*,

was a space geodetic satellite from CNES (Centre National d'Etudes Spatiales). *Stella* was mounted under SPOT-3, inside the payload adapter.

The two microsat-type satellites were ITAMSAT, now known as ITAM-SAT-OSCAR-26, and EYESAT-A, now called AMRAD-OSCAR-27. Both were built from designs originally from AMSAT-NA, but with changes and upgrades. IO-26 is dedicated to amateur radio service while AO-27 is primarily for commercial uses and was constructed by Interferometrics, Inc. of Vienna, Virginia.

The three SSTL-style spacecraft include KITSAT-B, now known as KITSAT-OSCAR-25, POSAT-1, which may be named POSAT-OSCAR-28 and HEALTHSAT-1. K-O-25 from SaTReC (Satellite Technology Research Center) of Korea is dedicated to amateur use. PO-28 from LNETI in Portugal is primarily to stimulate space application efforts in Portugal and may be available for some ham operation. HEALTHSAT-1 from SSTL is to be used by medical schools, universities, hospitals and documentation centers in Africa. It carries no equipment for amateur radio use, although its downlink is in the 420-430 MHz band. In Europe this is not a ham band.

The first signals heard from the new hamsats were those of AO-27 on 436.8 MHz. Within a day all of the satellites had been heard and were being loaded with software and successfully commanded by ground stations. The SSTL craft carry 16.5-foot-long gravity gradient booms that are deployed after all tumbling motion has been dampened by on-board computer control. PO-28 and HEALTHSAT-1 were both stabilized within a few days. Boom deployment was accomplished first on PO-28 and later on HEALTHSAT-1 by SSTL. Control of KO-25 was accomplished from the group in Korea.

Last month's column contained descriptions of the frequency plans for the new hamsats and further data on their operation. While they will provide more digital communications for hams on earth, other onboard experiments like KO-25's color camera will furnish new excitement for those interested in the scientific aspects of amateur radio satellites.

The End of ARSENE

On September 25th a group of French ground-control stations for *ARSENE*, the recently launched French hamsat, made a series of attempts to recover control of their satel-

lite. Since launch, *ARSENE* has had problems. The 2 meter transmitter did not function and commands to the satellite were not always executed.

The F5ELL UHF moonbounce station was used to send a long series of telecommands on 70cm to *ARSENE*. The F5ELL system includes a 26-foot parabolic dish and 2,000 watts power. F5PL monitored the *ARSENE* downlink on 2.4 GHz with a 23-foot dish. Nothing was heard after several at-

tempts. It is likely that the satellite has experienced a catastrophic failure. Some efforts will be made to regain control, but prospects are not high in France.

Many stations made contacts through the *ARSENE* transponder. It is hoped that the groups responsible for this ambitious satellite will use the experience gained to build another.

RTTY LOOP

Number 13 on your Feedback card

Amateur Radio Teletype

Marc I. Leavey, M.D., WA3AJR
6 Jenny Lane
Baltimore MD 21208

Last month, I hinted at a modification to the Flesher RTTY terminal unit that would enable it to run as an interface to some of the popular RTTY software. This month, thanks to information provided by Joe Masur AA5YA, of Perkins, Oklahoma, I can offer a way to accomplish this transformation.

This modification is for the Flesher TU-470 terminal unit. I do not have information regarding other Flesher units, but I'd like to hear of information developed in this vein by any of you.

General Information

Begin by unplugging the unit and removing the two rear screws. Slide the modem out of the case. Remove the one screw holding the main fuse and push it aside. For RS-232 operation, it is advisable to disable the loop supply by lifting CR7 and CR8. Then install a 4.7k 1/4 watt 5% resistor in the resistor position marked with "RX" between R20 and R25.

If you don't like to make up plugs, you can purchase a Radio Shack female DB9 to female DB9 serial cable, and cut it in two. You will have a spare three-foot piece for later use. All the cables will fit inside the DB25 connector housing.

You will have to enlarge the outlet hole some, or pick one that will fit. You can also purchase three Radio Shack audio cables, double male, and cut them in two, as you will need five total: three to the radio and two to the scope. You could add the extra cable and then have the choice of operating AFSK or FSK. When marking the quad board, mark jack, and the DB9 connector locations, leave enough room at the outer edge for the terminal unit case.

All of the cable grounds do not have to go to any special pins on the terminal unit, but pins 23 and 24 are not used. Use pins from 15 to 22 to make up the neatest arrangement, in any order possible.

Quad Jack Phono Board

Unsolder and remove the 25-pin connector from the PC board. Be careful not to damage the solder-through pads. Line up the quad jack board on the inside of the unit and mark with a pencil at each end on the

Switches Reversed And Vertical For Clarity

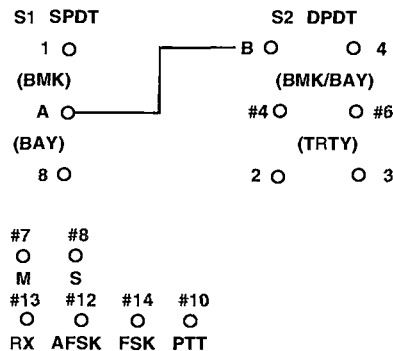

Figure 2. Switch detail wiring.

rear frame. With a small file or Dremel tool remove 3/16 inch of the PC board between your pencil marks, or until there is enough room to insert the phono board. Mark and drill the mounting holes for the phono board and set aside.

DB9 Connector

Remove the loop supply plug and unsolder the lead to the PC board. Mark and form this hole to fit the connector and drill the two mounting holes. Cut and solder a three-inch length of proper color-coded wire to each of the eight pins and set aside.

BUY AMERICAN, BETTER PRICE AND QUALITY

The SG2000 HF transceiver is type accepted for commercial and marine service made with traditional U.S. commercial radio quality (and of course it can be used on the ham bands also). While the Japanese radios have 2 final transistors that strain to put out 100 watts on the low bands and only 75-85 watts on ten meters, the SG2000 has 4 large transistors that loaf along at 150 watts on ALL THE BANDS INCLUDING 10 METERS! Some of the SG2000 features are: 1) A control head removable (no special kit necessary) up to 150" away from the rig, perfect for automobiles and boats. Up to 8 heads can be utilized and used as intercoms also. 2) The largest display of any HF transceiver. 3) 644 pre-programmed memories and 100 user programmable memories. 4) operable from -50F (-45C) to 185F (+85C). You want quality right? Here is what EVERY SG2000 must endure before they're shipped from the factory: 1) They're factory aligned, 2) EVERY SG2000 is keyed down at full power (CW 150 Watts) into an open antenna for about 10 seconds, then connected to a shorted antenna and keyed down for an additional 10 seconds. 3) EVERY SG2000 is put in the

"BURN-IN" rack and keyed down for 24 hours non-stop at full power CW. Don't try that with the foreign radios. 4) EVERY SG2000 is then re-checked for alignment and put in the "TORTURE RACK" where they are keyed on and off every 10 seconds for 24 hours. 5) The SG2000 is then re-evaluated and all control functions are verified to ensure that the microprocessor is up to spec. THEN AND ONLY THEN IS THE SG2000 ALLOWED TO LEAVE THE FACTORY.

The bottom line is price, you know how expensive commercial rigs are normally, until DEC 31 we are selling the SG2000 BELOW DEALER COST at only \$1,585.00 each!! That's a \$400.00 savings! We guarantee the best price.

The SG230 SMART-TUNER is the best HF autotuner at any price, and to promote a product that is made in the USA, we're offering it at the guaranteed best price of only \$449.00!! WHY THE SG230? BECAUSE: When you tune an antenna at its base you are resonating the antenna, instead of just matching the coax to the radio as with other tuners such as the AT50, etc. The result YOUR SIGNAL GETS OUT MUCH BETTER. The Kenwood AT50, AT450 and other similar tuners can only match 3:1 mismatches (YES only 3:1) so forget matching anything but a fairly decent antenna. The SG230 can match from 0.5 Ohm to 10 kilohm antennas (up to a 200:1 mismatch), so it can easily match random wires, dipoles, rain-gutters, shopping carts, etc. The result MORE POWER.

CIRCLE 384 ON READER SERVICE CARD

Figure 3. PC board connections.

Scope Outlets

Locate the two scope outlets between the phono jack board and the DB9 connector. Mark and drill the 1.4-inch mounting holes. Solder on wires as above and set aside.

Switches

Find the correct placement for the switches. Check to see that the fuse block can be mounted and that there is clearance, then drill a 1/4-inch hole for each switch. Do not install.

Wiring and Mounting Quad Board and Scope Jacks

Cut all lead lengths for neatness and short runs while making the con-

nections. Solder all the ground lugs on the quad board in series with one wire with enough lead on one end to go to the ground lug on the terminal unit and the other end to go to the scope outlet ground lugs. Solder a three-inch wire to each center lug on the quad board and mount the board. Install the scope jacks. Solder the quad board ground wire to the terminal unit ground lug and the other end to the scope jack ground lugs. Then add one more wire to any convenient ground pad on the PC board and back to a scope jack ground lug.

Solder the four quad board and the two scope wires to the following PC board pads:

10	PTT	(XmitP)
12	AFSK	(SendAudio)
13	RX	(RcvAudio)
14	FSK	(Mark/Space)
7	MARK	(ScopeM)
8	SPACE	(ScopeS)

DB9 Connector and Switches

Install the connector and solder PC board wires:

5	BLUE	(Signal Gnd)	to a ground pad
7	GRAY	(SendP)	to pad 25

Solder a three-inch wire to #4 and #6 on S2 and install. Solder one three-inch wire to A on S1 and install. Solder

A-S1 to B-S2 and to the PC board solder:

#4 to pad 4 (DmOutRS)
#6 to pad 6 (AfskInRS)
From the DB9 connector solder wires:
1 (RED) and 8 (WHITE) to S1
4 (GREEN), 2 (ORANGE), and 3 (YELLOW) to S2.
*** DOUBLE-CHECK YOUR WORK! ***

Mount the fuse block and the fuse. Slide the modem back into the case and secure with the two screws. This completes the modification to the terminal unit.

Any communication program that uses pins 2, 3, 5, and 7 of the run using the TRTY position. Operation details include the following:

Terminal Unit:	Serial cable to computer
	Front panel push-buttons to correct shift, etc.
Cables:	RX to radio audio OUT
AFSK:	AFSK to radio audio IN
	PTT to radio PTT jack
FSK:	FSK to radio MARK/SPACE/FSK input jack

formation on this rather extensive, but useful, modification. As he points out, with the ability of the Flesher TU-470 to work on these modes, there is no reason to cart one of these off to the flea market. Conversely, if you spot one at a bargain, you might just be inclined to give it a shot.

I look forward to hearing from you all, with the results of such future efforts. Thanks to Joe for the hard work, and all the information.

Now, having done all of this, getting the software to run with is a piece of cake. Just send a self-

addressed stamped envelope for a current list of the "RTTY Loop" software disks, collections of programs available for the IBM PC compatible computers out there. Email sent to me on CompuServe (75036.2501), Delphi (MarcWA3AJR), or America Online (MarcWA3AJR) will be similarly answered. I look forward to your comments and questions online, or in the mail. I hope all of you have a good holiday season, and with all that is happening in the world, may we all look forward to a 1994 of peace for all the peoples of the world. **73**

NEW KITS!

DRAWING: Showing DFD4 and PMB4 Kits in the new CA4M hardware package

The **HOWES DFD4** is an add-on Digital Readout for analogue receivers and transceivers. If you have an FRG7, and analogue FT101 or a similar type of rig, then the DFD4 has been designed with you in mind. The DFD4 is a frequency counter that can be programmed for any IF offset so it can be used with almost any radio, including the old Government surplus sets. It can also count down as well as up, so it is suitable for "reverse tuning" rigs too.

To make the DFD4 even more suitable, we now offer the **PMB4** Programmable Matrix as an optional kit. This enables you to switch between six different programmed offsets, so the DFD4 can be used with more than one radio, and to compensate for IF frequency differences when switching modes. Also new is the **CA4M** "hardware package." This contains a custom made case with pre-punched anodized aluminum front panel (see drawing above), plus switch, knob, BNC socket, nuts and bolts, etc. to enable you to achieve a high standard of finish for your project.

BUILD A QRP TRANSCEIVER!

To build a transceiver with our kits is a simple modular, step by step approach. You can start with the receiver, and then add on the transmitter at a later date if you wish. Various accessory kits are available to increase the facilities, these range from a simple signal meter for the receiver to extra filtering and of course, digital readout. We offer a matching range of "hardware packs" (case, knobs, etc.) to enable your station to look as good as factory equipment! Whether you fancy a single band CW transceiver, or more complex dual band SSB/CW rig, all these kits are designed to be within the scope of the ordinary home constructor. The well thought out designs and the backing of professional RF test facilities mean you can build with confidence!

Single band 40 or 80M CW transceiver:

DcRx 40 or DcRx 80 receiver kit.....	\$28.95
CTX 40 or CTX 80 transmitter kit.....	\$26.95
CVF 40 or CVF 80 VFO for TX & RX.....	\$19.95

Building Small DC Power Supplies, Part 1

Hams and other electronic hobbyists often need small, low-voltage, low-current, DC power supplies. Most solid-state circuits require these power supplies. Indeed, if you look at solid-state circuits published in this magazine you will see that +5 VDC, +9 VDC and +12 VDC are the most commonly specified DC power supply voltages. We also see the same voltages in negative polarity used sometimes, as well as variable voltages (e.g. 0-12 VDC). Current ratings for this class of DC power supply vary from 100 mA to 5 amperes, with 1 ampere being by far the most commonly seen. This month we will take a look at how these DC power supplies are selected and designed. While DC power supply theory has gone far beyond the material presented here (watts/cu. in. are way up and lbs./watt are way down in commercial supplies), these supply circuits are easy to build with components that are available at almost any parts distributor (including Radio Shack).

Safety First

The DC power supplies described in this article operate from 115 VAC, i.e. residential wall current. There is an unfortunate and very stupid belief that this type of current is only moderately dangerous. Indeed, when I worked as a biomedical equipment technician in a major hospital, I overheard an intern claim that 115 volts from the wall isn't dangerous because they taught him in medical school that it's the current not the voltage that kills. I leaned over the

table and asked him if he'd passed high school physics on his way to an MD degree. Allowing, rather arrogantly that he had, I asked him if he'd ever heard of Ohm's Law. I then muttered to some people who were with me, "If he learned the rest of his medical school lessons the way he learned that one, will someone please shoot him on sight if he comes into the emergency room while I'm unconscious." The real fact is simple and brutal . . . so don't ever forget it: 115 VAC from the wall is potentially fatal. IT WILL KILL YOU if given a chance. A few guidelines will help:

1. Never work on a circuit that is plugged in.
2. Work on a dry, insulated flooring (I keep a masonite mat under my workbench stool).
3. Use a 1:1 isolation transformer to convert the one-side grounded AC power lines to a floating local power system.

I can't give you all of the information you need for safety under all circumstances, so please, please, please use some good sense when working with AC power.

The Basic LVLC Power Supply

Figure 1 shows the basic low voltage low current (LVLC) DC power supply sans switching and fusing. The basic components of the power supply are: transformer (T1), rectifier (BR1), ripple filter capacitor (C1) and a bleeder resistor (R1). We will take a look at other components, such as voltage regulators, later. But first, let's discuss the function of the basic components.

Transformer. The transformer (T1) serves to reduce the AC voltage from the power mains to a level required by the DC circuits to be served by the power supply. We will shortly discuss

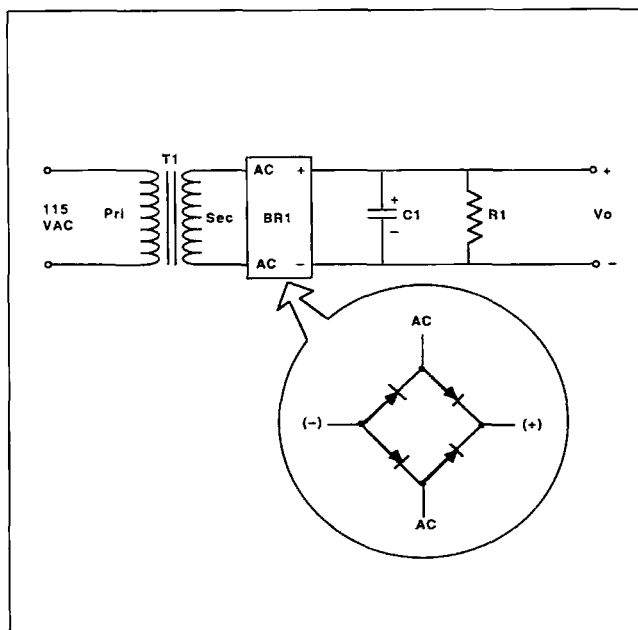

Figure 1. Basic full-wave rectified DC power supply.

what voltage and current ratings are needed for any given application.

Rectifier. The rectifier consists of diodes that convert bidirectional alternating current (Photo A) from the power mains to unidirectional pulsating DC (Photo B). There are two basic classes of pulsating DC: half-wave rectified and full-wave rectified. The half-wave rectified type only uses half of the AC input waveform, while the full-wave version (shown in Photo C) uses both halves of the AC waveform. Note that there are no spaces between the "humps" of the full-wave rectified version. In the half-wave rectified form there would be a flat line between humps representing the time taken by the rejected half wave. The output frequency of a half-wave rectifier equals the AC line frequency (e.g. 60 Hz in USA and Canada); the output frequency of the full-wave rectified pulsating DC is twice the line frequency (e.g. 120 Hz

in USA and Canada).

In Figure 1, a "bridge" rectifier is shown in the circuit. An inset shows the "innards" of the bridge rectifier, which is a ring of rectifier diodes.

Ripple filter. The pulsating DC from the rectifier is almost as useless to solid-state electronic circuits as AC. The ripple filter smooths the pulsating DC to make it much nearer to the pure kind-you-get-from-a-battery DC.

Bleeder resistor. The bleeder resistor serves two purposes. First, there is the issue of safety. Charged capacitors can be dangerous. While 12 VDC is not usually dangerous to intact humans, it can produce damage to circuits. In addition, if you wear a ring or watch or other jewelry, it is possible for the current stored in a large low-voltage capacitor to cause a nasty burn. Not likely, maybe, but life is full of nasty little "not-likely" surprises. The second use

Photo A. The 60 Hz AC input to rectifier.

Photo B. Full-wave rectified pulsating DC output of rectifier.

Photo C. a) Ripple with 100 μF filter; b) ripple with 1,000 μF filter.

for the resistor is to provide a minimal load to the rectifier. I've seen high-current low-voltage power supplies cause problems for marginally rated filter capacitors when the load was removed. It seemed that the pulsating DC peak voltage rose dramatically.

Component Ratings

The rectifier should be selected according to two ratings: peak inverse voltage (PIV), also called peak reverse voltage (PRV), and the forward current. The PIV rating is the highest reverse bias voltage that the diodes inside can tolerate without destruction. The general rule to follow is this: The minimum PIV rating should be greater than 2.83 times the RMS voltage rating of the transformer (T1) secondary winding. The reason for this value is that the diode will see the peak voltage from the transformer (1.414 Vrms), and this voltage charges the ripple filter capacitor (C1) to the same level. Thus, the reverse bias voltage seen by the rectifier is 2 X (1.414 Vrms), or about 2.83 Vrms. This minimum PIV rating is not usually a problem. Indeed, you can elimi-

nate the problem altogether if you use 1,000 volt PIV diodes or bridge rectifiers. If you go to most parts distributors, you will find 1,000 volt PIV ratings on most of the diodes available.

The transformer (T1) is selected to produce the required voltage. The average voltage across the filter capacitor after only a few cycles (milliseconds) will be about 0.9 times the peak voltage, or $VC1 = (0.9)(1.414)(V_{rms})$. Thus, a 12.6 VAC "filament" transformer will produce nearly 16 volts across the filter capacitor.

The current rating of the transformer secondary winding should be twice the expected maximum load current. For example, if you are building a 1 ampere DC power supply, then use a 2 ampere transformer. This guideline assumes that full-wave rectification is used. Many times I've violated this rule, and gotten away with it largely because the circuits I've built generally use a lot less than the maximum current. The maximum 1 ampere (1,000 mA) current drain usually only occurred briefly. However, 2 ampere transformers are easily available, so the guideline makes sense.

Also, if you violate the rule, check the transformer's operating temperature with the thumb test: Run the power supply for about five minutes, unplug it from the AC power mains (safety first!) and then quickly and gingerly touch the transformer's metal frame with your thumb. If it runs hot enough to burn then it's running at too high a current load.

The filter capacitor has two ratings to consider: capacitance and working voltage direct current (WVDC). The WVDC rating refers to the maximum voltage that the capacitor can tolerate on a continuous basis. I am generally quite conservative about this rating. First, assume a 20 percent tolerance: The minimum allowable WVDC rating should be 1.2 times the maximum pulsating DC that will be applied to it. I generally prefer a 2X margin, rather than 1.2 margin. Generally, whenever one sees a piece of equipment that has frequent problems with the filter capacitors "going west" it can be traced to using a supposedly safe but low margin of safety. In other words, for a power supply with a 12.6 volt transformer, which outputs about 16 volts peak, use a 25 VDC capacitor

at minimum, and prefer 35 WVDC and 50 WVDC models.

The capacitance required for the ripple filter depends on the degree of ripple suppression required, and the ripple frequency. The ripple frequency of half-wave rectified power supplies is 60 Hz in North America, so these require about twice the capacitance as full-wave rectified power supplies (120 Hz ripple frequency).

Photo Ca shows an AC-coupled (to eliminate DC offset) oscilloscope presentation of the ripple present on a lightly loaded 1 ampere 12 VDC power supply with a 100 μF filter capacitor (C1 in Figure 1). Without changing the settings of the oscilloscope, Photo Cb shows the same power supply, under the same conditions, when a 1,000 μF is used in place of the 100 μF capacitor. Note the substantial reduction of ripple.

In some cases, the ripple reduction of Photo Cb is good enough. However, there are many cases where a considerably better degree of ripple suppression is needed. Those cases require a voltage-regulated DC power supply... which is the subject of next month's column.

73

SCARED OF THE CODE?

IT'S A SNAP WITH THE ELEGANTLY SIMPLE MORSE TUTOR ADVANCED EDITION FOR BEGINNERS TO EXPERTS—AND BEYOND

Morse Code teaching software from GGTE is the most popular in the world—and for good reason. You'll learn quickest with the most modern teaching methods—including Farnsworth or standard code, on-screen flashcards, random characters, words and billions of conversations guaranteed to contain every required character every time—in 12 easy lessons.

Sneak through bothersome plateaus in one tenth of a word per minute steps. Or, create your own drills and play them, print them and save them to disk. Import, analyze and convert text to code for additional drills.

Get the software the ARRL sells and uses to create their practice and test tapes. Morse Tutor Advanced Edition is approved for VE exams at all levels. Morse Tutor is great—Morse Tutor Advanced Edition is even better—and it's in user selectable color. Order yours today.

For all MS-DOS computers (including laptops). Available at dealers, thru QST or 73 or send \$29.95 + \$3 S&H (CA residents add 7.75% tax) to: GGTE, P.O. Box 3405, Dept. MS, Newport Beach, CA 92659 Specify 5 1/4 or 3 1/2 inch disk (price includes 1 year of free upgrades)

UPDATES

Active Antenna Using a MOSFET by Ken Cornell W2IMB

Please refer to the above article in the March 1993 issue, page 32. The parts list correctly sets the values for RF chokes 1 and 2 at 1 millihenry; however, the schematic depicted them (incorrectly) as 1 microhenry RFCs. TNX to Victor Bennighl for spotting the mistake. The author makes another good point. He suggests that you set the R1 pot to its mid-point before applying power. (Adding a series resistor would provide an additional margin of safety for the MOSFET.)

Radio Direction Finding

Joe Moell P.E. KØOV
P.O. Box 2508
Fullerton CA 92633

Testing the Ramsey Foxhound

You can tell that a ham radio activity is gaining popularity when established manufacturers begin to supply equipment for it. Until recently, hidden transmitter hunters (sometimes called foxhunters or T-hunters) had to build their own gear or buy it from a few companies specializing in radio direction finding (RDF) sets, such as Doppler Systems and BMG Engineering.

The big three manufacturers from JA-land aren't making T-hunt products yet, but at least one well-known US mail order company has begun to supply this growing market. Last winter's Ramsey Electronics catalog announced two new items of foxhunting gear. The "SlyFox" transmitter is still futureware as of this writing, but the DF-1 "Foxhound" direction finder is available at hamfests, from dealers, and by mail order from the factory (see Photo A).

A Versatile TDOA Set

Mobile VHF T-hunters usually use a Doppler unit with its ring of antennas, or the amplitude-based RDF method (beam, attenuator, and S-meter). In contrast, the Foxhound is a "homing" type of RDF set. Homing

RDFs have two vertical antennas—dipoles in this case—spaced less than a half wavelength apart, plus some sort of left-right indication (LEDs, meter, or tone pitch change).

There are two look-alike kinds of homing RDFs: switched cardioid pattern and time-difference-of-arrival (TDOA). Of the two, hams prefer TDOA units because they work with unmodified VHF-FM transceivers and do not require an RF attenuator at the receiver input. The DF-1 is a TDOA unit, similar in principle to a number of sets that have been developed since the early 1980s.

RF diodes in the Foxhound switch the receiver input rapidly back and forth between the two antennas at about 1 kHz (see Figure 1). When the incoming signal wavefront arrives at one antenna before the other (as for transmitters #1 and #3), the antenna switching produces pulses out of the receiver's FM discriminator, heard as a lone mixed with the received audio.

The phase of these pulses is detected within the DF-1 circuitry, activating the left or right indicator as appropriate. When the two antennas are equidistant from the source (as is transmitter #2 in Figure 1), no tone is heard and no LEDs light. A sharp null in the tone gives a precise line of bearing to the fox.

Using a homing RDF set is easy. Watch the indicators and listen to the

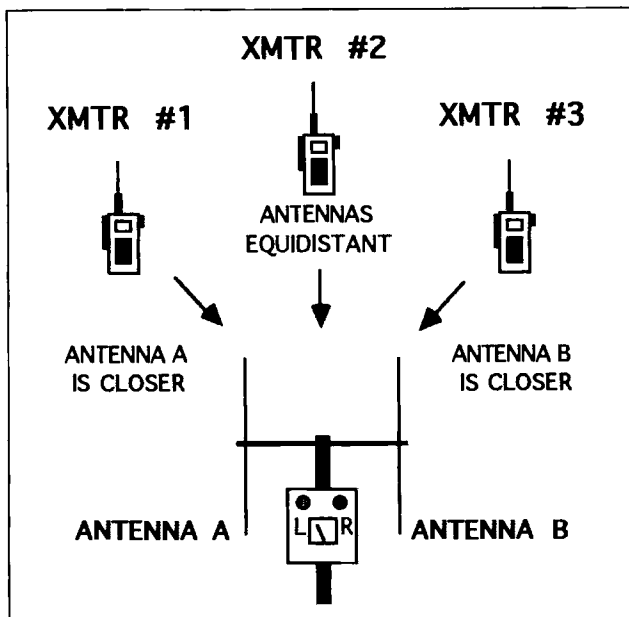

Figure 1. TDOA RDF sets such as the Ramsey Foxhound find direction by determining which of its two vertical antennas is closest to the transmitter.

RDF tone while you hold the unit and turn slowly. You should hear two distinct nulls in the RDF tone, 180 degrees apart. You are facing the direction of incoming signal when the tone is nulls and movement to the left makes the "turn right" indicator come on. Conversely, your movement to the right makes the "turn left" LED light. If the opposite happens, do an about-face and try again.

By walking, turning, and following the null and lights, you home in on the fox. The Foxhound is designed only for on-foot "sniffing." Using it in motion on a vehicle would be unsafe, unless you build a special rotating antenna system with extended coax lines so that the antenna pair is outside the vehicle and the rest is inside.

The DF-1's manual cover lines proclaim that it "works with any radio, any frequency." Not exactly. TDOA sets need carrier-type signals, such as CW or FM. They aren't designed to track SSB or broadband impulse noise. The receiver must have an FM detector. AM and product detector sets will not work with it.

The two TDOA antennas must be less than a free-space half-wavelength apart. The PVC-pipe-frame antenna pair described in the manual (23-inch spacing) is intended for 2 meters, but will work over a wide frequency range. You can use it with your extended-receive-range handheld or scanner to track signals in the business and maritime bands below 250 MHz. For higher bands, the dipoles must be shorter and closer.

Theoretically, the supplied whip set works on 6 meters, but the non-resonant antennas and short spacing results in too little DF tone from the receiver. A bigger antenna system is needed below 108 MHz. Portable

use of the DF-1 on 80-10 meters is not practical because an effective antenna set would be excessively large.

If At First...

The Model DF-1 kit (Photo B. Price \$59.95) includes a circuit board, all necessary components, meter, gain control, whip antennas, miniature coax, and instruction manual. You will need a case for physical protection and for meter and gain control mounting. The optional Model CDF case set (Photo C., \$12.95) includes a clamshell enclosure which is predrilled and lettered, plus all essential hardware.

An antenna framework is not provided. The manual shows how to make a frame for 2 meters from inexpensive PVC pipe and fittings. The whips mount on small circuit boards inside the pipe. (See Photo D.)

Ramsey supplied their Revision 1.0 kit for review. The circuit board was marked DF4 Rev 1.4 10/12/92. It took me one evening to populate the board and another to construct the antenna system. Aside from minor part discrepancies and some missing hardware, it went smoothly.

When I set up my test transmitter and powered up this early version, the performance was disappointing. Sometimes the meter would "hang" or bounce for no apparent reason. RDF indications were not trustworthy. The right indicator was on most of the time and the left indicator seldom came on.

Probing the DF-1 board with a scope showed clock noise and oscillation at the active tone filter output and on the Vcc lines. The favoring of one indicator appeared to be caused by asymmetry of the antenna switching waveform, which should be a

Photo A. Aha! It's in the trashcan! Jason McLaughlin KØBICZ shows how to "sniff" out a hidden 2 meter transmitter with the Ramsey Foxhound. The unit connects to the antenna and earphone jacks of his handie-talkie.

Photo B. The spacious circuit board is easy to assemble. For ease of troubleshooting, I used ribbon cable instead of the supplied short jumper wires to panel components. The Ramsey-recommended 9 volt battery is shown, but I later changed to 12 volt power.

Photo C. The DF-1 circuit board is designed to fit into the optional CDF plastic case. Coax and connector locations on the revised board are different from this original model. It's wise to order the case and board at the same time to be sure they are compatible.

50% square wave to minimize harmonics in the DF tone at the receiver output. A couple of electrolytic capacitors were installed according to the instructions, but were not observant of correct polarity for this circuit.

I suggested some circuit changes to Ramsey Electronics engineer Tom Hodge WA2YTM and he agreed to review the DF-1 design. A few weeks later, a Revision 1.3 kit arrived. Its new circuit board (DF1 Rev 2.0 5/13/93) had fixes to provide a square-wave switching waveform, better supply filtering, and proper capacitor polarity. Several glitches in the manual had been corrected and there were no missing parts.

After another session with the soldering iron (it went much faster the second time), the new board was ready to test. Now, with a fresh 9 volt battery, I was able to get good metering null and usable left-right indications with my test fox.

Raise the B+

The Foxhound uses a MF5 active filter IC, which is temperamental about its power source. When Vcc dropped from 9.5 to 7.8 volts after a few hours, it went into uncontrollable oscillation. Duracell specifies end-of-life of a standard MN1604 alkaline battery at 4.8 volts. Thus, much of the battery's capacity is wasted by replacing it at 7.8V.

I substituted a series pair of 6 volt Duracell 7K67 batteries in place of the MN1604 battery. These "J-size" batteries are widely sold for replacement in TV remote controls, etc. Each 7K67 has the same ampere-hour rating as an MN1604. Although DF-1's current drain is slightly higher at 12 volts than at 9 volts, the J's last much longer because they can be used to near end-of-life voltage.

Performance of the DF-1 is notice-

ably better on 12 volts, compared to 9 volts. The meter circuit is much more sensitive and the left-right indicators flicker less. I couldn't find holders for the J batteries and the tabs would not take solder, so I pried out the tabs, crimped them to stranded wires, and hooked the wires to the connector from an old 9V battery. Double-sticky foam tape holds the batteries to the board.

The Foxhound has a power jack on the bottom panel for external supply. If you don't mind another dangling wire, you can use it to supply 12 volts to the board. If you do this, be sure to remove all internal batteries. The steering diode in series with the battery was deleted when the board was revised. If you don't remove internal batteries, the external source will attempt to charge them with no current limiting. Damage to batteries or your supply could result.

Foxhound Pluses and Minuses

Most TDOA sets require you to listen carefully to the DF tone to detect the exact null. The DF-1 is the first set I have seen with a panel meter to help you find the null. Usually your ear is the best null detector, but the meter is useful when hunting in locations with lots of acoustic noise, or when there is heavy voice or tone modulation on the bunny's signal.

Plugging the DF-1's audio cable into your receiver disables its speaker. The only way to hear the hidden T and its tone null is to plug an earphone into a jack on the bottom of the DF-1. I don't like a tangling earphone cord when I'm tramping through the brush. Furthermore, the mini-jack supplied by Ramsey is the wrong size for my ICOM earplugs, so I added a 1-1/2-inch speaker inside the DF-1 case. The speaker is wired to the normally closed terminal on the

DF-1 earphone jack, so an earphone can still be used if desired.

With no audio from the radio, both LEDs are off. It's easy to forget to turn off the Foxhound's power after the hunt. To remind you to save the battery, you may wish to add an LED power-on indicator.

In Conclusion

The Foxhound adds sniffing capability to your RDF arsenal for less than 73 bucks. Its left-right LEDs give an unambiguous direction indication. The spacious circuit board is well documented to help you build and modify it to your particular needs. When powered by a 12 volt supply, its performance on 2 meters is comparable to competitive TDOA RDF sets for on-foot foxhunting.

If you already have an early model DF-1, I recommend upgrading it to the latest circuit for best performance. John Ramsey told me his company will provide modification instructions on request. Ramsey Electronics is at 793 Canning Parkway, Victor NY 14564; telephone: (716) 924-4560.

Remember that there are certain RDF situations where all TDOA units work poorly. Horizontally polarized signals are much more difficult to track than vertical, because signal reflections are enhanced relative to the direct signal on the vertical whips. Weak signals may be masked by noise from antenna switching. A properly polarized beam or quad is needed in those special situations.

Tracking in severe multipath (inside a building, for instance) is difficult with a TDOA, too. But when signals are strong, vertical, and in the clear, the TDOA will give sharper bearings than a beam, and bearings will be easy to get even if the fox transmitter is changing power.

Photo D. A close-up end view of one antenna. Ramsey supplies the telescoping whips, small circuit boards to mount them, and miniature coax. You provide the PVC pipe frame.

New Resources

At the beginning of every school year, I like to force myself to search out new resources to use in the classroom with my ham radio classes. There are lots of commercially prepared materials that are highly publicized that I use year after year to prepare the kids for the license exams. I realize, however, that it's important to continuously be on the lookout for new resources and new ideas.

With the delay of school opening in New York City due to the asbestos crisis, I've had time to peruse some wonderful new teaching aids and materials that I'll be adding to my program. In the spirit of sharing, I'll describe the new resources I'll be incorporating into my ham radio curriculum.

Alpha and Zulu

Riding The Airwaves With Alpha and Zulu by John Abbot K6YB is a delightful soft-covered book that uses comic book characters, the Phonetic

cos, to prepare you to take two different amateur radio license exams, the Novice and the No-Code Tech. One-hundred-and-twelve comic strips review all the questions and answers. If you look closely at the Phonetic characters you will notice that each one of their bodies is made up of Morse code "Dits" and "Dahs" that form the correct symbol for that character's letter.

After each cartoon page is a testing page. The answers may be found on the following page on the bottom left side. There are puzzles, connect the dots, word searches, games, and projects throughout the book.

This book will be a fine addition to any teacher's library. It retails for \$15 from Artsci, Inc., P.O. Box 1428, Burbank CA 91507; (818) 843-4080.

The Art of Science

If you're a teacher working with older or more advanced students you should take a look at a book called *The Art of Science* by Joe Carr K4IPV. This book is an excellent resource and guide for teachers and students alike that addresses the practical "how to do it" phase of scientific experimentation.

Joe discusses how to choose the

type of experiment best suited to your application, how to keep professional quality scientific records, how to make accurate measurements and correctly estimate errors, how to present your results like a "pro," how to think critically about your theories, and how to spot fallacies in the arguments of others.

For the serious students who participate in science fairs, there are valuable lessons in this book. Too often we forget to teach the basics of scientific inquiry and we neglect to give the students the tools they need to be creative yet exacting in their efforts.

The book is available from Hightext, P.O. Box 1489, Solana Beach CA 92075; (619) 793-4141.

Slow-Scan Program

The ham radio students in my classes always enjoy working with Slow-Scan TV. John Langner WB2OSZ has a terrific package available for \$229.95. Pasokon TV is the interface, software, and manual, assembled and tested.

Here are some features: It can send and receive all popular modes. The interface fits inside the computer. It can

LOOK WHAT'S NEW FROM DAIWA

.....Have You Seen These Great NEW Products From Daiwa?.....

MH-200 - Lightweight, folding "personal stereo"-type single earpiece headset and flexible boom mic. Inline locking or momentary P.T.T. switch. Models for Kenwood, Icom, Yaesu and others.

ME-300 - Tiny in-the-ear headset with high quality tie-clip mic and inline locking or momentary P.T.T. switch. For Kenwood, Icom, Yaesu and others.

MD-400 - Compact, high quality gooseneck-type desk mic with P.T.T. and up/down buttons. Deluxe weighted die-cast base. Superb audio. Complete with attractive foam windscreen. Models pre-wired for Kenwood, Icom and Yaesu.

Compact, Full Duplex, GaAsFET Pre-amps!

DLA-25B - The perfect companion for dual band HT's while mobile! 25+W kick on either band w/ 200mW to 6W drive for solid repeater coverage. From panel output meter, switchable, all-mode for CW/SSB.

DLA-50H - 50+W out on both 2 meters & 440MHz w/ 200mW to 15W drive. Plenty of power for those DX repeaters & reliable simplex operation. The perfect medium power dual band HT amp - and only from Daiwa!

DLA-80H - Heavy duty version, high power dual band linear amp. Full output (80+W VHF, 60+W UHF) from 3-25W drive - perfect for dual band HT's and mobile rigs! All-mode operation for CW/SSB, built-in fan for continuous-duty operation and more!

Low Power Operation

Michael Bryce WB8VGE
2225 Mayflower NW
Massillon OH 44646

[Editor's Note: Observant readers of this column noticed last month's material was a repeat of the column originally printed in June 1992. We don't know how this happened. Michael passed in a new column but we somehow substituted an old one. We apologize to Michael and to his loyal readers.—Ed.]

Back to the Future

A transmitter's output must be as clean as possible. Just because it only produces 5 watts of output is no excuse for a dirty signal. That's the purpose of the output filter—to make sure the signal is clean. This month, I'll show you how to design an output filter for your latest creation.

Of course, the reason we need an output filter in the first place is simple: A transistor amplifier generates buckets full of harmonics. Without a properly designed filter, these harmonics would cause all sorts of problems to other stations and even other services. Unfiltered transmitters can produce interference to devices not in the amateur bands, such as your neighbor's TV, stereo, toaster, and so on. Never place a transmitter on the air without a harmonic filter!

The Output Filter

So then, the purpose of an output filter is to keep unwanted harmonics from ever reaching the antenna. We do this by designing a filter to cut off at a frequency just above the one we want to keep. In a 40 meter transmitter, the operating frequency is 7 MHz, of course. A good cutoff frequency for our output filter would be just above 7 MHz. Most output filters for the 40 meter band have a cutoff frequency of 8

MHz. Some may be lower, some may be a bit higher, but all will be around this range.

Frequencies under 8 MHz will be allowed to pass to the antenna. Those above the cutoff frequency will be attenuated. Depending on the type of filter, this attenuation may be as great as 60 dB. The amount of attenuation required is based on the amount of RF power too. A 5 watt transmitter is allowed a greater amount of harmonics than a transmitter running 100 watts. Get your rule book out and you'll see that transmitters under 5 watts are to have their harmonic contents under 30 dB down. A 100 watt transmitter must have its harmonic contents reduced to 40 dB down from the fundamental frequency. In either case, the larger the number in terms of dB, the better the filter works.

The amount of attenuation required will determine the type of filter required. In many simple QRP transmitters, a single coil and two capacitors comprise the output filter. The more sections you have in the filter's design, the better the filter. The amount of attenuation is measured as ripple. The less ripple, the better the filter. Ripple is measured in dB.

The Coils

In today's filter circuits the coils are almost entirely wound on toroid cores. Not only is a toroid self-shielding, it also allows a large amount of inductance in a very small package. You would be hard pressed to find a output filter in today's equipment not using some sort of toroid cores.

In filter design, we need to know several fundamental items: cutoff frequency, core type, input and output impedance, power handling capacity, and physical size.

Given a cutoff frequency in MHz, we need to first find the proper core to use

in our output filter. This is best done by looking up the core's characteristics on a chart or table. You can get one of these tables from any of the companies selling cores. The ARRL Handbook is also a good source.

As a good rule of thumb, a type 2 core is good from 80 meters to about 30 meters. Above 30 meters, a type 6 core is a good choice. I've seen some applications where a type 2 core was used for 20 meters and type 6 material on 30 meters.

Don't be duped into thinking the color of the core is etched in glass. I've been bitten by this bug before. Just because the core is yellow, don't assume it is type 6 material. Be especially careful of hamfest or surplus toroid cores. A mislabeled core in your next rig could be a hard problem to track down.

The amount of inductance required will also dictate the required core. There are two more factors that need to be addressed: wire size and, to a certain extent, output power.

I have found that wire size has little to do with the final inductance of a coil wound on a core. Before I get hate mail from Mike WA8, let me say most hams don't have the specialized equipment to measure the exact inductance of a homemade coil. If the plans call for 24 turns of number 26 gauge wire but all you have in your junk box is 24 gauge, then use it. You won't be able to tell any difference in the final output of your project.

On the other hand, if the coil needs to be wound with six turns of number 12 gauge wire, you can't really substitute six turns of number 22 gauge wire either. Most high-power (high-current) applications will require a thicker gauge of wire to handle the current flow, be it RF or DC. The core size and type will also have to be determined to handle the power at the required inductance. A larger core will be required to hold larger wire to get the same amount of turns required.

Inductance Values

Output filters of 0.01 dB of ripple

have become somewhat standard with QRP transmitters. A better filter would have 0.1 dB of ripple. You'll see about a two percent loss in power, but you'll gain a 10 dB improvement in attenuation.

The desired filter frequency will be: $F_c = F_o (1.15)$. Use 7.2 MHz for F_o : $F_c = 7.2 \times 1.15 = 8.25$ MHz. The filter cutoff frequency (F_c) is 8.25 MHz.

From the chart, for a 0.1 dB ripple, seven-pole filter, the value for L_1 is 11.32. So, $L_1 - L_3 = 11.32 / 8.25 = 1.35$ μ H.

From the same chart, the value for $L_2 = 12.52$. So... $L_2 = 12.52 / 8.25 = 1.5$ μ H.

This tells us the required amount of inductance for each of the coils in our transmitter. The number of turns will be calculated next, but first we have to see what type of core we'll use.

I happen to have a handful of T-50-2 cores, so that's what I'll use. According to the table supplied by Amidon, a 2 mix core is good from 1 to 30 MHz. This same table provides us with an important factor required for calculating the number of turns: the AL value. This tells you the μ H per 100 turns of wire on the core. The AL value for the T-50-2 core is 50.

$$\text{So, turns required} = \frac{100 \sqrt{\text{desired } L (\mu\text{H})}}{\text{AL value.}}$$

$$L_1 - L_3 = 100 \sqrt{\frac{1.35}{50}}$$

L_1 and L_3 require 16 turns of wire.

$$L_2 = 100 \sqrt{\frac{1.5}{50}}$$

L_2 requires 15 turns of wire.

Capacitor Values

This takes care of the coils. Now for the capacitors required in the filter. Again from the table, C_1 and $C_4 = 3759.8$. $C_1 - C_4 = 3759.8 / 8.28$. C_1 and C_4 are 454 pF; use the standard value of 470 pF.

$C_2 - C_3 = 6673.9 / 8.28$. C_2 and C_3 are 806 pF; use the next standard value of 820 pF.

By using the information available to us, we can calculate the values required to keep our transmitters clean. Give the old calculator a try and create your own QRP machine.

Getting Started with TCP/IP, Part 3

Wow! I guess you ARE interested in getting a TCP/IP station on the air. At least that is the way it looks from here. I have received *hundreds* of email requests for information about software and IP addresses. My Internet mailbox overflowed, so I lost some of the queries, and I just couldn't possibly answer all those requests—not enough time in the day. So, I'll do the best I can, and try to clear up the confusion that a transposition of letters caused in the first installment of this series, and give you the best information that I have about IP address coordinators.

In the first column I told you to get a copy of JNOS version 1.08c from UCSD.EDU via anonymous FTP. Well, forget that. Here is the CORRECT information:

Location: UCSD.EDU (note the correction from UCSD.EDU)

Directory: hamradio/packet/tcpip/wg7j

Filename: JNOS107B.EXE

Those of you who have managed to get later versions of JNOS, this is fine. The choice of 1.07b is based on its stability and availability, but later versions will work. Keep this in mind because this version is available in the directory noted above. The 1.07b version will be available on the 73 BBS, in the "Packet and Computers" area (8). You can reach the 73 BBS at (603) 924-9343, 2400 baud, 8N1. Note that this is a relatively large file and the slow speed of the 73 BBS should convince you to try other places first.

Uncoordinated Coordination

I thought most of you would be able to find your local AMPR coordinator, though I expected a few requests for help. Well, after receiving hundreds of messages via Internet mail, I realized that maybe some of you were having some trouble. I have to do something, but answering each of your cries for help is not a practical

route. So, here (in the sidebar) is the list of the official volunteer AMPR coordinators. THIS IS ALL THE INFORMATION THAT I HAVE. I cannot tell you how to contact these people or exactly which one is the coordinator for your location.

Look on the list and take your best shot. It has been sorted by location, to make it easier for you. Also, the last column is the *subnet* for the coordinator's area. This can also be a clue for you. Find someone with an IP address and look for the matching subnet. Remember that these people are volunteers—please be friendly and courteous with your request. If you think that you might want to run more than one station, request more than one address. Though the specific information that the coordinator will need may vary from place to place, if you contact them via packet radio, try to include at least the stuff below to decrease your chance of being asked to provide more information:

Your name.

Your call.

A mailing address.

A phone number.

The county, town or city, and zip code where the station will be located.

You may have to wait a little while for a reply, try to be patient. If you want to get started, but don't yet have an address, you can use the official "test" network. This is any address in the 44.128.XXX.XXX range.

An Important Note About Packet Radio

While I always enjoy corresponding with you via packet radio, I simply cannot do business that way. Because I do not want to have even the appearance of impropriety, I just cannot answer any mail that refers to the column and then asks for help. Please, if you need help, use commercial email or paper mail. I can be reached on the Internet:

jsloman@bix.com

and by US mail:

N1EWO

P.O. BOX 636

Franklin IN 46131

Thanks for your understanding.

Note, too, that I still want to hear from

you on the amateur packet network. Please, just restrict this traffic to pleasantries or questions that relate to ham stuff with no reference to the column.

More Than Error Correction

Though I had planned to get started on the tutorial this month, I had to clear up the confusion caused by typos and whatnot. Now I don't want to completely frustrate those of you who have managed to get the software and an IP address, so let's take what space is left to at least begin the tutorial. (Next month will be dedicated to the tutorial.)

JNOS and Its Files

The heart of making JNOS work is a set of text files that configure the program and provide information to it. Though they all must be in good shape for things to work, the central focus is on a configuration file called AUTOEXEC.NOS. Like a combination of DOS' CONFIG.SYS and AUTOEXEC.BAT, AUTOEXEC.NOS contains hardware and software configuration information and commands for the program to carry out on start-up. It is the arcane and not-so-logical stuff in this file that will make or break your station.

Unfortunately, the exact format and syntax of AUTOEXEC.NOS varies not only among implementations of NOS, but even among versions of the SAME implementation. To get you started with JNOS, we'll look at one of the most confusing and absolutely required sections of AUTOEXEC.NOS as it works with JNOS (and most other NOSs, thank goodness).

The section is reproduced here in Figure 1. These are the statement(s) that attach the communication device(s) to the program. Our example here is to connect a TNC to a comm port. Later on we'll look at more advanced stuff like Ethernet.

Any of the lines that begin with "#" are comments, and shown are lines for all four comm ports. The active one is com1, since it is not

preceded by "#".

The attach command instructs the program to connect a hardware device to the program. The parameter "asy" is an abbreviation for "asynchronous," the type of communications device. The next value "0x3f8" is the base address of the communications port, you probably don't need to change the values from the standard ones listed here. Following the base address is the IRQ (interrupt). This is also a standard value for each port. The next parameter, "AX25," tells JNOS what sort of interface this will be. There are other values which we will discuss later.

The value "tnc0" is an arbitrary name that is used to refer to the interface you are creating. This name can be nearly anything, and should probably NOT be tnc0. Many users name it by frequency—01, 03, 05, etc.—to make it easier to understand what is going on. If your station will not necessarily stay on one frequency, name it anything that seems meaningful to you.

The next two numbers are buffers; don't change these until you know more. This is another advanced topic which we will discuss. The last number is the baud rate of the port. Note that it is set to 4800 here. Why? Because the program may have difficulty decoding the information from the TNC if it comes at a higher rate, but the messages from the TNC will seem intolerably slow at 1200 or 2400. This is a good compromise. One way to tell if you have the port speed set too high is the presence of corrupted or "nonsense" calls in the "just heard" list.

Keep It Simple, Stupid

The other absolute requirement for NOS to operate is that the TNC be made to operate in KISS (Keep It Simple, Stupid) mode. In this mode, JNOS takes over the operation of the TNC. There is a small script included as part of the AUTOEXEC.NOS that is designed to turn your TNC's KISS mode on (most TNC command sets require a simple "KISS ON" com-

mand). We will cover this part of the file next month. In the meantime, if the TNC does not seem to initialize correctly try this: Talk to the TNC with

any communications program, ensuring that the communications speed (baud rate) matches the one you chose in the AUTOEXEC.NOS.

Check your manual for how to get your TNC into KISS mode. Send the command(s) and exit the program. Start NOS, and you should be all set.

Next time we'll get into more meaty stuff. Sorry for the confusion—I hope it's cleared up now. 'Til then 73 de N1EWO.

Super Portable ATV Repeater

One night while I was visiting with Mike Henkoski KC6CCC, we decided to try to build a lightweight ATV repeater with a minimum number of components. The idea was to come up with a compact battery-operated system that could be easily transported (or even backpacked) to a remote site to act as a temporary relay during a special event or emergency. To test it out in the field we chose to launch it into the stratosphere with a weather balloon. From our planned maximum altitude of 100,000 feet we could potentially link up two ATV stations that were 800 miles apart (provided the repeater was midway between them).

The System

In order to eliminate the filtering and shielding required of an in-band repeater, we went with a crossband system that received on 915 MHz and transmitted on 434 MHz (see Figure 1). Mike KC6CCC designed a homebrew receiver taken from a commercial surveillance system that provided us with a complete receive board on 915 MHz that outputted video and au-

dio directly. Note that you could also use a crystal-controlled receive board with a companion IF strip available from P.C. Electronics for this part of the repeater.

The transmitter consisted of a P.C. Electronics 80 milliwatt micro-ATV board (with companion subcarrier strip) which drove a PA5 power amplifier module. This combination gave us a 5 watt sync tip output while only drawing a little over 1 amp of current.

The repeater ID consisted of an Eltronics VDG-1 with an external timer. It would be better to go with a video-operated relay (eg: a VOR-2) instead of the timer, but we used what we had in the shack at the moment.

To keep the total repeater as light as possible, we used five D-cell lithium batteries (7.5 Ah). Although usually very pricey, we found a good source of very reasonably priced surplus lithium packs (10 D-cells) from S&G Photographic, telephone: (215) 474-7663. One pack should give you around 10 hours of operation (five hours using just five cells). Where weight is not critical, you will probably want to use a 5 Ah rechargeable gell-cell pack.

Mike KC6CCC built a pair of quadrifilar helix antennas (one for each band) for our flight test since we wanted a good pattern below the balloon repeater. For a hilltop or remote site, you will probably want to go with

Photo A. Mike KC6CCC, Mike WA6SVT, and Curt N6TWB fill three balloons to lift the ATV repeater.

a linearly polarized omni or gain antenna system, depending on the area you want to link up.

The Flight Test

About 24 hours after tossing the potential repeater components into a big pile, we had the ATV repeater wired up and mounted in a lightweight styrofoam package. The modules were fastened to a piece of foamcore and surrounded with one-inch-thick styrofoam for insulation. We powered up the repeater and discovered that the transmitter section was badly overloading the receiver board. Fortunately, Mike Collis WA6SVT arrived on the scene and went to work bypassing the power leads while Mike KC6CCC shielded the receiver with

copper foil. After spacing the antennas about five feet apart (the 434 MHz helix dangled below the payload), we finally came up with a fully functional crossband ATV repeater that performed well. The entire repeater (complete with batteries) weighed in at a mere six pounds!

We loaded everything up and headed for the hills above KC6CCC's house in San Clemente. We decided to launch the repeater with three small weather balloons. As Mike WA6SVT held onto the repeater, the balloons whipped about in a strong 10-15 knot wind. The possibility of crashing the repeater into the ground at takeoff was very real. Mike solved the problem by walking over to the edge of a cliff and tossing the re-

Photo B. The completed ATV repeater next to its styrofoam enclosure.

Figure 1. Block diagram of the lightweight ATV repeater system.

peater over the side! Just like taking off in a hang glider, the balloon repeater headed slowly off to the edge of space.

The 5 watt transmitter power provided most stations within 100 miles of the repeater with P5 color reception throughout the three-hour flight. Two stations in the area were capable of transmitting up to the repeater on 915 MHz during our flight test. We were able to send color video through the repeater from the launch site when we had our antennas oriented properly and Sam Lutweiler K6VLM could access the repeater with P2-P5 signal levels from his location in La Mirada (about 50 miles to the north). He could even repeat through the system using just 1 watt of uplink power.

It was such a clear day that we were able to see the balloons with binoculars and even observed two of them bursting at 72,000 feet. The repeater started descending with one

balloon still intact and landed near the top of Mt. Elsinore near a dirt bike park.

Curt N6TWB and Jon N6ZYX Toumanian were chasing the repeater with DF gear and quickly spotted the remaining balloon bobbing above the repeater as it rested on a ridge about a mile ahead of them. As they rounded a curve and arrived at the landing site, they were surprised to see that the balloon and repeater had disappeared. They walked past some nearby pickup trucks at the dirt bike park and heard a strangely familiar beeping sound coming from the back of one of the trucks. It turned out that one of the dirt bikers, Tom Vetter, had beaten the chase team to the repeater and was about to call us for the reward! Although our wallets were a little thinner, we did recover the repeater. The repeater survived the flight in excellent condition and we hope to fly it again soon to test it out with different combi-

Photo C. Sam K6VLM's 1 watt signal, as seen via the airborne repeater.

nations of in and out frequencies. For example, a future flight may use 434 MHz in with either 919.25 or 1253.25 MHz as the output.

Microwave Waveguide Construction: Detector Mounts and Transitions

This month I would like to pass on information about constructing microwave waveguide components. I want to cover diode detector transitions and other bits and pieces, in response to several questions. Where can you find these? The answer is they can be found at swap meets and such. If you can't find them, you can construct them at home out of very junky waveguide scrap, with just a little effort. The construction doesn't require close tolerance work; suitable devices can be constructed in any home workshop. The units you construct should have a usable frequency span of an octave or more.

The best waveguide to select for construction is brass because it can be soldered with a heavy soldering iron (300W or so), or even a small torch is OK. Aluminum can be used,

despite the fact that it cannot be soldered without special fluxes. This can be done, but I feel that it's not very effective. I don't use the special aluminum soldering fluxes. They are costly, and my experience with them has given poor results. Let's get on with the construction and remove the veil of secrecy from these useful microwave components.

Finding Waveguide

Where do you get material for this construction project? Well, waveguide can be purchased new from suppliers at nearly \$4 a foot, but most suppliers have a minimum order value far in excess of what you are probably willing to spend, pretty much removing that source from our list. What I prefer to do to remedy this situation and to keep prices low is to select some scrap sections of used waveguide at swap meets. These can be part of an attenuator or other obscure Old World test or filter section. These waveguide pieces can best be described as a short section of guide with something in the middle of the section that is not desirable and would make good doorstep materi-

Figure 1. Waveguide mixer construction. Brass tube: size to fit BNC connector. Brass choke: 0.250" long, with hole to fit 1N23 diode, and other end soldered to connector. Insulate from brass tube with Scotch tape. Ground the diode's bottom end in the brass block. The dimension for Xg is 1/4 wavelength, modified by the velocity change in waveguide, or (Xg). The length is 1/4 Xg. For further data, see the BASIC program in the sidebar to compute Xg.

al. The modification is to cut off the middle section and toss it into the junk box or scrap metal box.

The more obscure the guide section looks, the more inexpensive the

part will be. I always try to locate something in the surplus market that was bent into something special, with an appearance more like a pile of worms than waveguide. The reason

for picking up these obscure sections of waveguide is simple: We only want the flange end and about an inch of waveguide behind it for our applications. The rest can be junked. Usually these special bent pieces will yield two flanges and short sections of guide. That's all we need to construct either a detector mount or a transition to coaxial connectors for our use. In these applications we can use SMA, BNC, or even type N coaxial connectors.

Any connector can be used; the important point is where the coaxial connector's pin is located in the waveguide in respect to the shorted rear end of the guide. Basically, the detector mount construction is almost the same as for a transition. The detector mount difference is due to the diode decoupling capacitance. In this way it varies from the transition, which does not require any decoupling. Whichever unit you construct, the design principles are the same.

Let's start with a detector mount construction and its capacitance decoupling. To obtain this output capacitance for the diode detector, a small circular tower (pipe) is built on top of the waveguide to accommodate this capacitor. The capacitor is constructed out of a solid piece of brass round stock that is cut to size, allowing a fit when insulated inside the tower pipe. This makes it an RF short at microwave levels, hence it is an RF

Photo 'A. Example of a homemade horn constructed from PC board and a transition for 24 GHz. Note the small coax connector center for size comparisons. Photo by WA5VJB.

choke. Together with the diode mounted in the waveguide, this tower connects with the business end of the diode and connects it to the coaxial connector for easy use. The RFC (brass rod) decouples the RF at microwave frequencies, giving good isolation from the waveguide RF to de-

tor output at low frequency RF, usually 145 MHz. The RFC is not apparent at 145 MHz.

Well now, how about a little boring math? This is needed to construct these devices for your desired frequency or different waveguide type. This formula is good not only on 10

GHz but also on almost any frequency for which you have a section of waveguide, even 24 GHz. The calculations are needed to determine where to position the diode or coaxial probe. The computer program in the sidebar gives the required spacing needed for proper operation. I have made the pro-

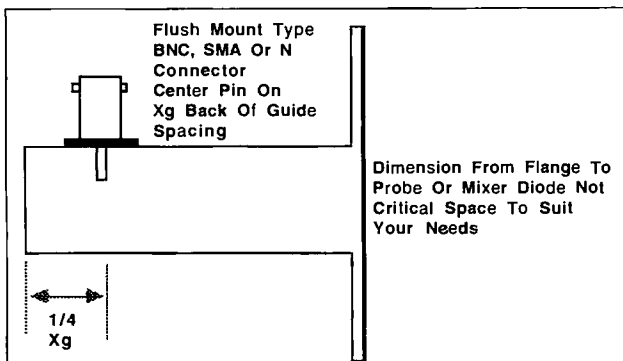

Figure 2. Waveguide transition construction. Solder the coax connector direct through the mounting hole in the top of the waveguide. The pin on the connector should be 0.1" long for 24 GHz and 0.2" long for 10 GHz. SMA center pin diameter is OK for 24 GHz; for 10 GHz the diameter of the pin should be 0.050".

gram short and easy to use—no frills here.

The calculations depend on just what type of waveguide you are using and what frequency you wish to optimize your device for. Table 1 includes some of the more popular waveguide types and lists both their "WR" number and the older equivalent "WG" number. To match waveguide up I have also included the guides' inner and outer dimensions so you can compare the guide you have to the table for identification. Normally, for 10 GHz WG-16 is used, but WG-17 can also

be used. As a matter of fact, you can mix sections of both WG-16 and WG-17 without much extra loss; this works reasonably well. Just bolt up as best you can with the smaller waveguide centered about the larger waveguide's opening and drill the larger guide bolt holes to match the smaller bolt pattern. Then connect them up.

I don't mean to say that you can use several conversions between two points, but rather that in a line of, say, WG-16 you can terminate the end in WG-17 with little change in loss compared to a proper termination. We

have observed additional losses in the 0.4 dB range for this adapting. Not much of a price to pay for making something usable. See Table 1 for dimensions for your frequency selection. XG is the dimension for a guide wavelength, which is shorter than free-space wavelength.

Computing Guide Wavelengths

The guide wavelength program (see sidebar) in BASIC requires only the broad width of the waveguide and the frequency of operation to compute the guide wavelength. Guide wavelength is different from free-space wavelength and must be accounted for. "X" is calculated for free-space wavelength at sea level and some humidity is entered into the calculation. It uses a fudge factor instead of using the more familiar 300,000 figure. The guide wavelength is then divided by 4 (step 84) and this is the quarter-wavelength dimension needed for the probe or diode placement in your selected waveguide. The probe is centered about this dimension from the rear inside point of the waveguide in both applications.

Now for some practical applications in the real world. If you go and check these calculations out against existing transitions and mixer diode mounts that you might have, I hesitate to tell you, but there will be some glaring errors. Primarily, the errors in sizing will

happen because the part being measured was designed for some other frequency that we are not aware of. When we think of material being suitable for 10 GHz, remember that some of the commercial equipment was designed for use at 12 GHz and this could be part of the error observed in the calculations. Any other errors can be attributed to the free service that I offer, and will be taken in the same regard. To place a "forgiveness" factor in any calculations you could make the rear wall a little longer and place a solid metal plug to fill the inner waveguide dimensions. Adjusting this metallic plug will allow any error in assembly to be effectively adjusted out of the unit. It requires more construction but is a fine-tuning method.

Construction Details

Actual constructed mounts are depicted in Figure 1 for the transition and Figure 2 for the waveguide mixer mount. I think it has been shown that being off a few thousands will not have much effect on the quality of your mount. However, when you construct anything with waveguide, having any material like solder inside the guide will have a detrimental effect and will increase the device's loss. These materials include various solders and fluxes, water, any obvious metal particles, or burrs on the edges. The mating flanges can be commer-

cial or homemade, and should be flat to mate well with each other.

The only trick with old flanges or home-brew flanges is to make sure that the surfaces are flat. To be sure, lightly file any rough edges to approximately flat. Then place a sheet of light grade emery or sandpaper on a small section of junk glass. Sand the flange and waveguide with the flange face-down on top of the glass plate. Sand flat on the sandpaper/glass, moving with a circular motion. In this way you will guarantee that the flatness of the glass sanding table will be transferred to the waveguide flange. After a few passes on this sanding table it will be obvious how well this method works. The high and low spots are very evident on the sanding just completed. When the flange is uniform in appearance, it is flat.

Well, that's it for transitions. The main point is: Don't let junky-looking waveguide remain in the scrap heap. Even the most worry-looking section can be put to use if it has a one- or two-inch straight section. The coaxial part of the probe should enter the waveguide about half of the waveguide's small dimension for good coupling. SMA connectors have quite small probes. In this case, build it out with a small brass tube about 1/16 inch in diameter to make the probe wider. Remember, dimensions can be very forgiving. High accuracy is not required in construction. A milling machine is not required.

Mailbox

Raymond Clancy of Westminster, California, writes, "Where can I locate surplus LNAs to convert, as per your May '93 column?"

Well, Raymond, that's the paradoxical question, as they are where you find them. I have responded to several newspaper advertisements for satellite service and have had lots of rejections, but one strike. I believe this method could be tried in almost any city to attempt to locate some used

LNAs. These are not much use to commercial dealers; these dealers should be your best bet. Some dealers don't want to talk about used units, they'd rather do a sales pitch on new systems. I guess some business owners don't want to redistribute used material, perhaps because they fear competition for new sales. In this case stress that the units will be torn apart and that they are not going back into satellite service, but into amateur radio service instead.

Some shops will hustle you for a high price, without knowing the LNA's condition, presumably because they are still trying to sell you a new unit. You just have to get by that barrier. For the time being, since you are located in the Los Angeles area, I would suggest you go to the swap meets, particularly at TRW, which is in the Los Angeles area. Cost for most units as is should be no more than \$5. That's the typical price I have found for swap meet units. And don't overlook the local non-ham swap meets—there are a lot of people getting rid of their satellite systems. The bottom line is that if the asking price for an old 80-to-100-degree LNA is over \$5, they're asking too much. That is, unless the unit is new, from stock, and never used. I paid \$25 for my first LNA and \$35 for the first 12 GHz LNB. What a price to pay for education.

Mark WOPMX wants information on the Mitsubishi M57716. I looked at my reference material and could not come up with the data. RF Parts Co., a 73 advertiser, lists many of the modules for sale, but not the M57716. What Mark needs is the pinout information and spec sheet for the device. Does anyone out there have the information for him? He is at 4810 Indiana St., Golden CO 80403. I am sending off to Mitsubishi for data on their modules, and I hope to get back to you soon with data.

Well, as I write this column I am getting ready for the last weekend of the ARRL 10 GHz contest. The plan

TABLE 1.

WR #	WG #	OD-inch	ID-inch	Freq. GHz
WR-90	16	1.0 X .5	.9 X .4	8 - 12.4
WR-75	17		.75 X .375	10 - 15

WR-34	21	.420 X .250	.340 X .170	22 - 33

Figures for WG-16 (8 TO 12.4 GHz):

Frequency	10000	10050	10368	10500	MHz
XG=	29.978	29.828	28.914	28.550	MM
XG=	39.703	39.359	37.320	36.553	MM

Figures for WR-42 (18 TO 26 GHz):

Frequency	24000	24193	24240	MHz
XG=	12.491	12.391	12.362	MM
XG=	15.407	15.221	15.167	MM

Formula to figure your own:

Xg = Guide Wavelength

Xg = $X / \sqrt{(X/2a)^2}$ where X = wavelength in MM and

a = Guide ID width (WG-16 = .9 inch)

this month is to operate near our local area and get as much activity up and running as possible. I will be operating SSB with 10 watts power output to a 30-inch dish. I plan to bring my older system, a wideband FM unit, to be able to work those stations using wideband. This year N6IZW and I plan to test a video system with our narrow-band rigs on 10 GHz. W6VLF and N6OYJ plan to do similar work at the other end of the test link. The test will be to attempt a two-way contact on 10 GHz video. It's just a preliminary test

and I'll fill you in on the results next month.

Don't let video operation or SSB operation displace wideband FM operation. All modes have their place, and I have had lots of fun with wideband FM just experimenting and trying different modes of operation.

Well, that's it for this month. As always, I will be glad to answer questions concerning this and other related subjects. Please send an SASE for a prompt reply. Best, 73 Chuck WB6IGP.

The Case of the Mystery Rig

I'm going to assume that, because you read this column, you're at least somewhat technically inclined. So, I can also assume that you have been to hamfests and have occasionally picked up a "mutl" of some kind, mostly because it was cheap and it looked like a challenge. I know I've bought things I couldn't possibly use, just for the puzzle they presented, or because I rationalized I could sell them after I fixed them. (That almost always turned out to be a bad idea which resulted in my working for about \$4 an hour.) Nonetheless, I've enjoyed owning some of the "mystery rigs" that have followed me home now and then, and some of them are still in active use in my station.

What First?

OK, you bought a radio or some other electronic marvel for next to nothing. You know it doesn't work. Where to start? Well, before you plug it in or insert batteries, consider taking a look inside. You might be surprised at what isn't in there! Recently, I picked up a

Uniden 10 meter rig for a ridiculously low \$10. The seller didn't hide the fact that it didn't work, but I sure was surprised to find that the microprocessor had been removed. Ouch.

If the radio looks complete, go ahead and apply power. One exception would be in the case of antique-vintage gear whose electrolytic capacitors might not have seen voltage in many years. By simply turning such things on, you might literally blow those caps to smithereens! A Variac is very helpful with that kind of equipment. Another exception would be if you see any signs of a short: burned parts or a charred PC board. There's no sense in repeating a disaster.

With modern, solid-state gear, a Variac is a bad idea. First of all, modern electrolytics don't blow up (well, not very often, anyway), and second, many devices employ switching power supplies or regulators, and they don't like the gradual power approach one bit. Most just won't work at all below a certain voltage, but will suddenly spring into action above their thresholds, thus defeating the purpose of gradually raising the power. And some will actually malfunction on low voltage in such a way that you think something's broken when it isn't. So, go for the gusto and give it the juice. Just remember, where

there's smoke there's fire, and you sure don't want one on your workbench; if you see any smoke, turn the thing off quickly.

Zip

Most likely, though, what you'll see is nothing at all. Or, perhaps, the pilot lights or display will come on but nothing else will happen. Can you fix such a beast?

Sure, why not? Naturally, the best thing you can do is get the schematic. For a currently available or recent-vintage rig, that should be no problem. Unfortunately, many hamfest treasures are older or of oddball origin, and you may have trouble getting the data. If you have packet radio capability, I strongly suggest you put up a notice looking for help. I recently did that after I brought home a Santic HT-1200 2 meter walkie. This older radio falls into the worst of both categories: it's old and it's relatively obscure. Yet, within a week I had the diagram and owner's manual in my hand, thanks to a caring ham who also had a broken '1200.

If you've got the diagram, you should be looking at a fairly straightforward repair job. That is, if the previous owner hasn't already botched the rig's insides. Unless the price is *really* low (as it was on the '1200), I avoid any gear which has had obvious tampering. There's an old saying about driving a car: Always drive as if everyone else is crazy except you. I feel the same way about technical work: Everybody else is incompetent. Obviously, that isn't really true, but enough people are that trusting another's work is asking for big trouble.

Which Came First . . .

When exploring a broken rig with a muddy history, it can be hard to tell which problems were original and which were the result of incompetent repair attempts. Let's examine the case of that Santic walkie; it's a great example of what you can run into. When I got it, it had an obviously destroyed tantalum capacitor. The seller pointed to it and told me that "that resistor is blown." That's all that's wrong." The component misidentification and the lack of the radio's back cover told me I was in for some real detective work.

I hadn't yet gotten the schematic but, luckily, there was enough left of the capacitor that I could read its value. The part was charred and the top of it was completely missing. From experience, I knew that the most likely cause of that kind of catastrophic failure in a tantalum is reversed polarity. That's about the worst thing you can do to a radio. Uh oh, could someone really have made that mistake?

It didn't seem likely. The battery pack obviously had been replaced, because its wires had been spliced onto the old connector. But, the positive terminal was connected to the red wire, and the negative to the black, so that seemed normal. Plus, the external power jack had a series protection diode, so reversed polarity there wouldn't make it to the inside. Hmmm. I guess that cap must have blown for some other reason.

More Clues

After replacing the cap, I applied power to the rig through the external power jack. Naturally, the thing didn't

Fast Packet Ticket!

The PackTwin™ Wireless Communications System

Thinking about the move to packet radio? Or have you already tried 1200 baud packet only to become quickly discouraged?

At Gracilis, we've got the ticket to the kind of speed you're looking for.

Using our PackTwin system with your existing IBM®-PC or compatible, you'll easily be able to communicate with other packet radio stations at rates of 9600 or 19,200 baud. If higher speeds are desired, the popular WA4DSY modem can be constructed and added to provide operation at 56,000bps.

When you order our PackTwin Wireless Communications System, you'll get a plug-in 'n'-play 9600/19,200 baud system, complete with modem and palm-size two watt UHF transceiver. You supply the PC and antenna—We supply the rest!

Consider these important features...

- Exclusive use of the PC's DMA channels provides an upgrade path to 1Mbps
- A second channel is included that can be used to provide a separate RS-232 or RS-422 interface
- Free software provides access to AX.25 and TCP/IP networks
- Free firmware updates

work. Wait a minute, the display came up for a second or two and then quit. A quick check revealed that the blown cap was part of a regulator circuit consisting of a transistor and a zener diode; the zener symbol marked on the PC board was the tip-off that it was a regulator. Both components were blown. Too much voltage? I still couldn't be sure. I replaced them and tried again. This time, the display came on and stayed on, and the keypad even worked (!), but there still was no audio and no transmit. Apparently, nothing but the micro was getting power. Scoping all the pins on the audio power amp chip showed that none had any voltage. I assumed that no power was getting to most of the rig (I was wrong, as you shall see). At this point, the hunt became fruitless because, without the diagram, it just wasn't possible to follow the maze of wires to find out where the power was disappearing. I put the rig away and nearly forgot about it.

A Map

When the schematic arrived, the chase was back on. The first thing I discovered was that the seemingly impenetrable forest of wires and transistors was actually a fairly simple electronic TX/RX switching circuit. But, the Q numbers in the diagram didn't match the ones on the board! Which transistor was which? Wait a minute, there's another schematic in here, and it has the right numbers. They must have had more than one version of the board.

Now that I had the correct schematic, I quickly found that the transmit switch transistor was blown. I popped in

another one, and the TX LED now worked when I pressed the PTT. I hooked the rig to my dummy load/wattmeter and keyed up. Nothing; the transmitter wasn't working. But I figured that, if I could get the receiver to go, the rest would fall into place. So, I ignored the transmitter and focused on why I had no audio. Why wasn't that chip getting power?

It Ain't Supposed To

Following what appeared to be the DC line of the audio amp chip (the big electrolytic to ground gave it away), I came to . . . a transistor. I should have known: The amp chip wasn't getting power because the squelch circuit was keeping it turned off. Sure enough, the other side of that transistor had full voltage. And, the transistor was good. So, there was something wrong with the squelch circuit. I followed the line back through a couple of transistors to the squelch output of the detector chip and scoped it while I turned the squelch control back and forth. Sure enough, it jumped up and down just fine. That meant that the detector chip was getting power and was, in fact, working. Next, I checked each of the three transistors between it and the squelch transistor. They were good. So were the two diodes. So why the heck wasn't this thing working?

Arrggggg

I must have spent over an hour going around in circles with this thing. Then I saw it. The wire going to "point B," which was one end of a small coil connected to one of those squelch tran-

sistors, was supposed to be for an optional tone decoder, which this radio did not have. That wire shouldn't have been there, yet there it was, going to the microprocessor board. And wait a minute, there was supposed to be a wire sending an "unmute" signal from the micro connected to another point only about a quarter of an inch away. And it wasn't there! You guessed it: Somebody had broken the wire and resoldered it in the wrong place. I moved it back and, wow, the receiver came to life! Now I was getting somewhere.

Can You Hear Me?

A quick check on the wattmeter showed that the transmitter still wasn't working. The diagram showed that the unmute signal enabled the transmitter as well as the receiver, so I had hoped that everything would be fixed. Obviously, the transmitter still wasn't getting power. Or was it? I had never actually listened for it; perhaps it was worth a try.

I set the frequency to 0.52 and keyed it up into the dummy load while listening on my other rig. Son of a gun, there it was, dead on frequency and with good audio! My victory thrill turned to sudden defeat when I realized what that meant: a dead final. Yuck. Sure enough, the final was connected right across the incoming DC line, before the regulator. Nothing there to protect it, and, if the polarity had in fact been reversed, that final would have been a forward-biased diode directly to ground; pretty much a dead short. But then I noticed that there was a 1 ohm resistor

between the transistor and the DC line. An ohmmeter check showed it to be 2.6k ohms! I popped in a new resistor and, wham!, 4 watts out, just like it was supposed to be. The resistor had blown, protecting the transistor.

So, the radio was fixed. Well, almost. I was about to consider it finished when I took another look at the battery pack. Yup, the positive goes to the red wire, which goes to . . . I looked at the PC board and saw that positive was going to ground. Backward. That connector must not have been the original one, and the previous owner had just assumed the wire coding would be the same. So that was it: The radio had been connected backwards after all. Case solved.

A Thought

Many people assume that a reversed-polarity rig will be completely destroyed. Certainly, reversing the polarity is pretty destructive. Often, however, the regulators and semiconductor switches which are directly connected to the DC line will blow, protecting the rest of the circuitry. Sometimes, as in this case, most of the radio will be fine and well worth fixing.

The End

I hope this little excursion has helped you see what you can be up against when you don't know who else has been inside your new find. Never assume anything, and happy hunting! Until next time, 73 de KB1UM. Hey, anybody happen to have the back for a Santec HT-1200? I have one in good working order that could use it. **E7**

LOOK WHAT'S NEW FROM DAIWA

.....Have You Seen These Great NEW Products From Daiwa?.....

Antenna Tuners

CNW-420 - World famous Daiwa cross needle antenna tuner better than ever! Switchable average or PEP reading, backlit cross needle movement. 20 and 200 watt scales. Built-in 2-position antenna switch. Covers 1.8-30MHz in 11 bands.

CNW-727 - Daiwa's unique high quality VHF and UHF antenna tuner! Separate tuner sections for popular 2 meter & UHF bands. Handles 200 watts. Tune your 2m and UHF antenna systems for maximum efficiency, low loss!

For Your Boat, Plane..High Quality 24VDC - 13.8VDC DC To DC Converters

SD-303FII - Attractive desktop DC-DC converter: full front panel switchable voltage & current metering, convenient lighter socket, heavy-duty binding posts and 2 sets of spring-clip DC outputs! A hefty 30 amps output at 13.8VDC with 20-28VDC input - enough for most any high power application!

SD-412II - Compact, easy mount 12amp output model with the size and look of a 30 watt 2m amplifier. Heavy-duty binding posts, lighter socket outputs, large heat sink and more!

SD-416II - Larger 16 amp output model with heavy-duty wrap around heat sink. Front panel binding-posts and lighter socket outputs. 20-28VDC input, plus many more features!

Available at your favorite Dealer Today!

ID-8 Automatic Morse Station Identifier

Compatible with Commercial, Public Safety, and Amateur Radio applications. Uses include Repeater Identifiers, Base Station Identifiers, Beacons, CW Memory Keys, etc. Great for F.C.C. ID Compliance.

- Miniature in size, 1.85" x 1.12" x 0.35"
- Totally RF immune.
- All connections made with micro-miniature plug and socket with color coded wires attached
- CMOS microprocessor for low voltage, low current operation: 5 to 20 VDC unregulated at 6ma
- Low distortion, low impedance, adjustable sine-wave output: 0 to 4 volts peak to peak
- Crystal controlled for high accuracy
- Transmitter PTT output (to key transmitter while ID is being sent), is an open collector transistor that will handle 80 VDC at 300ma
- Field programmable with SUPPLIED keyboard
- Confirmation tone to indicate accepted parameter plus tones to indicate programming error
- All programming is stored in a non-volatile EEPROM which may be altered at any time
- Message length over 200 characters long
- Trigger ID with active high or low
- Inhibit ID with active high or low. Will hold off ID until channel is clear of traffic
- Generates repeater courtesy tone at end of user transmission if enabled
- Double sided tape and mounting hardware supplied for quick mounting
- Operating temperature range, -30 degrees C to +65 degrees C
- Full one year warranty when returned to the factory for repair
- Immediate one day delivery

Programmable Features

- Eight programmable, selectable, messages
- CW speed from 1 to 99 WPM
- ID interval timer from 1-99 minutes
- ID hold off timer from 0-99 seconds
- CW tone frequency from 100 Hz to 3050 Hz
- Front porch delay interval from 0 to 9.9 seconds
- CW or MCW operation

\$89.95 each

programming keyboard included

Notes from FN42

I received a phone call from Dave Benedict W8REN of Troy, Michigan, one evening. I guess that isn't too spectacular, but he had always wanted to know what the "Notes from FN42" meant. Well, for those of you who are involved in VHF/UHF contesting it might not be too good a question, but for the rest of you it might make you wonder.

Somewhere in the "dungeon" I have a booklet from the ARRL explaining the grid system of the earth, but it seems to be hiding, so here comes my simple (hopefully) explanation.

The earth is divided up into grid squares, each measuring 10 degrees of latitude (600 nautical miles) and 20 degrees of longitude (0 nautical miles at the poles and 1,200 nautical miles at the equator). Each square is given a two-letter designation. Each of those squares is further divided into 100 squares, each one degree of latitude and two degrees of longitude with 00 in the southwest corner and 99 in the northeast corner. The coordinates of Peterborough, New Hampshire, are approximately 42° 52.5'N and 71° 57'W. Those coordinates fall into the FN primary square and 42 secondary square bounded by 42° to 43° latitude and 70° to 72° longitude, thus FN42. Hopefully this explanation has not confused anyone.

Regular readers of this column know I'm always trying to get others involved in this wonderful hobby of ours. I try to keep my eye out for examples of people getting involved and report them in this column.

One of those examples is Chris Edsorn N0CUH. Chris works at the Crocheted Mountain Rehabilitation Center in Greenfield, New Hampshire. I remember talking to him on one of the local repeaters when he moved into the area. He was looking for some hams in the local area to help him start a ham club at the center. I am happy to report that he found some help and is very busy developing a ham club and teaching those with disabilities the joy of ham radio.

I attended the open house at their new ham shack. One room in the basement of a building has been turned into operating positions and meeting space. Operating the day of my visit were a 2 meter FM transceiver, a 2 meter packet station, an HF station, and a computer used to learn Morse code. There are approximately six operating positions with coax hookups and both AC and DC power available.

The room was very busy that day

and very crowded with young people in wheelchairs and on crutches, some helping with the operation of the equipment and others providing information to new young people who came to find out what was happening. Several of the older ham volunteers were there. They had traveled over two hours to get there, and they had done it many times before to help install the antennas and ready the shack. That's dedication, folks, and getting involved!

I was very heartened to see one young lady in a wheelchair spell her name in Morse code on a practice oscillator and to observe the joy in her eyes when she realized what she had done. WOW! What an experience!

Do you want that same kind of joy? It doesn't have to come from working with disabled young people like Chris does. It can come from helping with classes or testing sessions, or helping with public service during emergencies or worthwhile public events. Foster the use of ham radio on the air. Be positive in your attitude toward amateur radio. Don't be part of a problem, be part of the solution.

Finally, December is a holy month for many of our world's religions. I wish all of you the joy, peace, and prosperity that you deserve. May our world's troubles be solved and peace to all mankind endure.

Happy Holidays! 73, Amie N1BAC.

Roundup

Mellish Reef Letter from Murray D. Adams, WA4DAN: Mellish Reef is located at coordinates 17° 24' S, 155° 51' E. Herald's Beacon Inlet is the only part of the reef that remains above sea level at high tide—it is not much more than a sandbar. It's been over 4-1/2 years since the last Mellish DXpedition, but in January 1989 a group reported that the islet was approximately 150' wide by 800' long.

Since the last operation, a couple of major storms have passed through that area; hopefully things have not changed drastically during this interval. The islet is basically pear-shaped. The intent of our operation is to set up two separate, completely self-contained sites as far apart physically as possible to try to reduce adjacent station intermod. One site will be at the north end and the other site will be at the south end.

One site will contain three HF stations while the other site will have two HF plus one 6 meter station. They will strive to listen as much as possible in the U.S. General class bands.

All DXpeditions have certain logistical difficulties to overcome. Mellish Reef is no exception. Heat (there's absolutely no shade) is a concern, along with the effects of salt spray on the equipment and antennas. Fitful rest on

Photo A. The beautiful QSL of Monk Apollo SV2ASP.

this type of DXpedition is a rarity. For some insight on this, read the fascinating account of the AHIA/Howland Island DXpedition earlier this year.

The Mellish Reef team has spent the last six months planning and working on the logistics for this DXpedition. We all look forward to contacting you from the reef.

The callsign for the operation is VK9MM. The operators are: VK4CCR, VK2BEX, V73C, K5VT, VK2BJL, P29DX, WA4DAN, and G3WGV.

We plan to operate CW, SSB, and RTTY.

Power will be supplied by one 4 KVA and two 3.5 KVA generators. 850 liters of fuel will be transported, and in addition, 80 liters of oil.

Equipment has been donated by Dick Smith Electronics, Coman Antenna Co. Australia, Emtronics Australia, GAP Antenna Products, Cushcraft Corp., Heil Sound, Dunestar Systems, and Oklahoma Communication Center.

On arrival, the team hopes to quickly get a couple of the stations operational using one yagi and one vertical while the rest of the team is ferrying gear to the two sites and assembling antennas, tents, etc.

The QSL manager will be Bill Horner VK4CRR, 26 Iron Street, Gympie QLD 4570, Australia. Please include SASE/SAE + \$1/IRCs. Any donations will be gratefully received and used to offset the high cost of the DXpedition. QSLing will commence by December 1, 1993.

Many thanks to all of the major DX foundations, many national regional and local DX clubs, and literally hundreds of individual DXers whose support has made this DXpedition possible. Our primary objective is to work as many stations as possible and to give as many who need it a new country.

[As most of you DXers realize, the Mellish Reef DXpedition completed its operation several months ago. This report did not arrive at 73 in time for advance notice. I hope to receive an update from WA4DAN in the future.—Amie]

USA/Mt. Athos Letter from Walery Sawka KB2FIV: I was more than hap-

py to see Father Apollo's SV2ASP statement printed in 73 magazine. Let me explain.

About eight years ago, I visited Mt. Athos for the first time. I fell in love with the beauty, people, and spiritual values of the place. It is still a very unique place on our planet. I have been traveling there every year since, not as a tourist, but as someone who shares. I work with them, pray with them, and share their humble life.

I am also a ham and faithful reader of 73 magazine. Through a short note, I learned about the existence of Father Apollo. After a strenuous walk through rough mountains, we met in the magnificent Byzantine Monastery of Dochiariou. He proudly displayed his 2 meter rig. It was an old Kenwood and some wire dipoles. He loved them and was talking about it with gleaming eyes. He had problems, not only with the Administration of Mount Athos to get an operating permit, but with the power supply as well. The monastery operates the electric generator only during the day for using power tools. The rigid monastery schedule doesn't leave much time for hamming. The donated old Japanese generator is not only noisy but produces 117 volts instead of the European 220 volts.

Father Apollo is working hard, long days and prays long nights. He is friendly, gentle, and always smiling. Two years ago disaster struck—a canister of cooking gas exploded! Father Apollo survived with bad burns of the face and was almost blinded! His being able to see is one of the miracles of the Holy Mountain. And then, last year, there was the unpleasant experience with unauthorized transmission of DJ6SI. With my knowledge of Mt. Athos and all the documentation given to me, I don't have even the slightest doubt that it was illegal. How can the ARRL pass such easy judgment?

Father Apollo's problem might happen to us, too—we can become the victims of unauthorized transmissions, tampering with packets, etc. In my opinion, Father Apollo has become the victim, and I hope his faith in decency and people won't be disturbed again. I am including his famous QSL card so

that others can see what they are missing.

If anyone has any questions, please contact me: Walery Sawka KB2FIV, Box 290, New York City NY 10028.

OKINAWA JAPAN

David Cowhig J76CBQ/WA1LBP
AmCon Naha
FBU PSC 556, Box 840
FPO AP 96372-0840

June brought Telecom Week and a demonstration of satellite communications, packet radio, ham TV, ham facsimile using the old NEC mini-fax machines available cheaply here, and eyeball rag-chews in Urasoe City. The packet radio stations used the DX-TERM Japanese language packet radio software which automatically switches into the display mode when it hits a NAPLPS videotext message on packet radio. It was very startling to be watching the kana and kanji of a Japanese packet message moving up the screen when suddenly the computer started to draw a full-color cartoon or map. You have probably seen videotext pictures on the news or weather bulletin channel of your local cable TV system. At the Telecom Week hamfest aspiring YL ham 10-year-old Toshitaka Ayaka, daughter of Toshitaka-san JS6KVP, told me she will take the August JARL ham class in Naha. A video-equipped Apple computer generated this picture of Ayaka, her 6-year-old brother Tsutomu, Toshitaka-san JS6KVP and myself.

NAPLPS attracted many followers in Japan, where drawing cartoons is a very popular hobby. *CQ Ham Radio*, Japan's biggest ham magazine, runs works of art by ham cartoonists every month. Some of these images make it onto the Japanese packet radio and

landline computer networks as NAPLPS images. NAPLPS image files are a series of graphics commands which the receiving computer executes to draw a picture. A nice drawing can be sent in a file of 1 or 2 kilobytes which would require 50 kilobytes or more if sent as a bit-mapped image. You can find NAPLPS software such as NALVIEW.ZIP and other series of NAPLPS programs in ZIP files beginning with NALP written by enthusiastic Japanese hams such as Roy JM1VSP Kurashima Akihisa on the AMRAD BBS (703) 734-1387, or the Virginia Connection BBS (703) 648-1841 with its super-fast modem. Looking at this collection of pictures and playing with the software will give you an idea of what NAPLPS is like. I translated the documentation from Japanese several years ago. Creating a good NAPLPS file is hard. I would like to blame NAPLPS but the real problem is that I am not an artist.

I hope that all hams throughout the world are enjoying learning about the Okinawan culture and life. My fellow hams on the island are certainly enjoying seeing their news in 73.

PHILIPPINES

DX stations who wish to operate temporarily during their stay in the Philippines must apply for a reciprocal license before bringing their transceiver(s) into the Philippines. Section IX of the Philippine Amateur Radio Regulations states that "The NTC may authorize a person who is a resident and citizen of a foreign country to operate his or her amateur station while temporarily in the Philippines provided he or she is a holder of an appropriate ama-

Photo B. Computer-generated picture from Okinawa.

teur station license and an operator's license or certificate issued by the government of the country of which he or she is a citizen and provided that the same country has a formal or an informal reciprocal agreement with the Philippines. He or she should be encouraged to affiliate with a local amateur club for better camaraderie and fellowship." All reciprocal license call signs have their original call suffixed by the word "portable" or "mobile," followed by the appropriate DU district number (from /DU1 to /DU9 only, no /DU0). For example, N1BAC will sign N1BAC/DU6 or DU6/N1BAC in Negros Island (IOTA OC-129) when he goes on a DXpedition here. [I'm ready, Wayne! When do we leave?—Arnie] NTC Reciprocal Licenses are usually issued with a maximum effectivity period of one year and can be renewed 30 days before the date of the expiration of the license.

The following documents are required when applying for an NTC reciprocal license: (1) Application letter stating your request to apply for a reciprocal; (2) Reciprocity agreement or Informal agreement with the Philippines. Either document should come from your country's amateur licensing authority, certifying that it has issued or will issue an amateur radio reciprocal license to citizens of the Philippines who are holders of Philippine Amateur Radio licenses and/or certificates to be able to operate his or her amateur radio station with appropriate privileges while in your country; (3) A certified copy of your license; (4) A list of the transceiver(s) (brand, model, and serial number) you plan to bring to the Philippines; and (5) Certification from your country's amateur radio licensing authority stating it has no objection to your operating your amateur radio station in the Philippines.

COLLINS 208U-3A

2.5 KW POWER AMPLIFIER for 2 29.9999 MHz SSB-AM-CW using 4CX5000A tube. RF input 25-100 MW for rated output; auto-tune capable. Includes URG-II compatible control modules and most manual copies. Requires 200-250 VAC 3 phase 30 A; 73x33x31, 1020 lbs sh. USED-not tested less 4CX5000A \$4200

TAIWAN

Tim Chen BV2A
PO Box 30-547
Taipei, Taiwan
China

Hello, everybody! I would like to submit this statement about our activities and the progress of ham radio on this island to the readers of 73 magazine.

All hams are delighted to hear the long-awaited announcement that the Chinese Taipei Amateur Radio League (CTARL) has become the 126th member society in the International Amateur Radio Union (IARU) and its Region III since October 30 and November 7, 1992, respectively. We tried hard over the past years to obtain those very memberships. We are grateful to all those societies over the world for favoring us the votes (71 votes without a nay, unanimous!). We are encouraged and believe that we will have more and

closer relationships and cooperation with all concerned in the future.

There was a celebration party held in the Mandarin Hotel, Taipei, on December 12, 1992. Not less than 400 hams and guests were present, and the buffet dinner was served from the evening until midnight. Special guests attending were Legislator Y. S. Lin; Mr. C. Y. Chen, Director of Post and Telecommunications Department, M.O.C.; Mr. Chen Yen, Division Chief of International Department, M.O.F.A.; and many other VIPs.

In April, the government's examination for ham operators will take place in central Taiwan—Taichung City. We are expecting 2,000 or more candidates and those passing will turn out 700 more new stations at the end of the year. The continuing growth of hams will make it possible to hold two examinations every year, beginning in 1993.

CTARL members in Taipei, Taichung, and Kaohsiung cities are in full swing, organized to serve the newcomers. Usually they supply cold drinks, stationery, and code practice for the last dash at the venue at no charge.

The CTARL is going to re-elect the second-term directors and president. I will be retired from CTARL service, but will never cease to be a ham. All visitors from abroad should call as usual if they happen to be in Taipei.

Next month I will report on the expedition to initiate the first BV9 on Quemoy Island.

Amateur Software and Hardware for the Commodore User

ART-1

NEVER SAY DIE

Continued from page 4

my own enthusiasm, and you probably could care less about music. Well, that's a shame to miss seeing or hearing beauty. It's probably too late now. Your parents should have opened the worlds of music, art, and books to you. Yeah, art. I've been in every major art museum in the world and have just about every book on Hopper's paintings ever published. Did I tell you about the time I was working on a Guggenheim grant at the Guggenheim Museum on Fifth Avenue? Probably did.

Say, I'm beginning to ramble like Old Indiana Jones. Have you been enjoying the summer Indiana Jones series? I particularly enjoyed the one where he met Sri Krishnamurti. I've always enjoyed K's books and used to go to his lectures in New York. I liked his philosophy, which they got across nicely in the Young Indiana Jones program. I suppose religious fanatics might be upset by his ideas.

Speaking of religion (a no-no), a recent *Newsweek* had an interesting article about the latest scientific ideas on how life got started. I was pleased to see that there are more and more scientists leaning toward the Hoyle theory. I think I mentioned Hoyle's book, *Evolution From Space*, sometime back. I like things to make sense, and this does.

If I can make some time I'd like to start doing a series of audio tapes which would discuss the music, books, amateur radio, and other things I'd like to share with others. A few die-hards got irritated with me at Dayton because I didn't talk about amateur radio the whole time. Heck, I talked for two hours and was only barely started. I did talk about my concerns about the ability of us continuing to keep our priceless frequencies without giving anything much in return as a quid pro quo. But then I've been writing about that theme for years. I'd like to get around to more hamfests to talk, but between music and computer shows, plus a little work to do around here, I've boxed myself in. If I get some spare time I'd like to organize my library and get the bam in better shape. And maybe chase a little DX. I was having fun on 10m until the sunspots killed it.

As soon as I can get set up with a remote transmitter system I'll be looking for duplex contacts . . . mostly on 20m. Oh yes, don't forget, if you talk to JY1, pass along my regards, and tell him I'd like to help him get his educational system out of the basement. Jordan has the only school system they've measured that's worse than ours. We're talking world-class bad, which is a real shame. That's a terrible legacy for his people. The bright side is that their kids are only just a little dumber than ours. But we're working

diligently on dumbing our kids down even more, so who knows.

Now, please don't forget to write. Let's at least see a QSL with a rating for a book, gadget, or kit.

Ham Club Responsibilities. How Does Your Club Shape Up?

In my reports to the New Hampshire Economic Development Commission and our humongous citizen's legislature, I was expressing my frustration at their allowing excessively lousy overpriced schools, ridiculously expensive health care, poverty, rampant crime, drugs, and so on to continue . . . while there are some practical, inexpensive solutions to all these problems. I happened to look up the word "civics" in my dictionary. Check it out, since it applies to our beloved hobby, too. "The division of political science dealing with the privileges and obligations of citizenship."

It's the quid pro quo bit again. If you want to enjoy the privileges of citizenship, then you must fulfill your obligations. You can mull over the many privileges you enjoy as an American citizen, then start considering how well you're handling your attendant obligations. Like being an informed voter, for instance. If you were informed, you wouldn't keep sending the same old crooks to Congress, term after term . . . and then ask for term limits to stop you from doing this.

So, what has this to do with ama-

teur radio? The quid is our privilege of using billions of dollars worth of frequencies as our playthings. The quo is our obligation to provide something in return, other than abuse.

What should we be doing? Well, we're supposed to be a technical hobby . . . a training ground for youngsters . . . and for each other. Considering the complications of technology today, it's difficult for us to become experts on everything. This is where our clubs can help. Suppose every club meeting started off with a technical talk by one of the members. One might explain how RTTY works. Another about SSTV. Others could explain about packet, satellite communications, aurora, moonbounce, fox hunting, and so on. You might assign club members the responsibility to learn about spread spectrum, digital radio, digital video, compression algorithms, fractal compression, orthogonal frequency division multiplex, and so on . . . and then have them explain these concepts to the club. Many hands make light work and it's exciting to learn new things. You might even find more hams coming to club meetings, and more getting interested in trying new modes and bands.

I keep reading all of the ham club newsletters I get, hoping to see signs that some of our clubs are taking our obligations as hams seriously. I'm not encouraged. How about your club? Let

TRIPP LITE DC POWER SUPPLIES: YOUR KEY TO GREAT COMMUNICATIONS!

According to 73 Magazine,
it's performance that
"never misses a beat."

Tripp Lite gives you:

- Great looks and high performance
- Crowbar protection
- Excellent regulation and line noise isolation
- Units available from 3 to 60 amps
- Competitive prices

PR Series DC power supplies are ideal for powering practically everything in your ham shack, including low band rigs, 2 meter and UHF radios.

Sample a unit today!

Why buy a TNC?

PC HF FAX + PC SWL \$179.00

SPECIAL COMBINATION OFFER

For a limited time, if you order PC HF FAX \$99 (see our other ad in this issue), you can add our new and improved PC SWL 3.0 for \$80.00 instead of our regular low price of \$99.00.

PC SWL contains the hardware, software, instructions and frequency lists needed to allow you to receive a vast variety of digital broadcasts transmitted over shortwave radio. All you need is any IBM PC or compatible computer and an SSB shortwave receiver. The product consists of:

Demodulator
Digital Signal Processing Software
200 Page Tutorial Reference Manual
World wide Utility Frequency List
Tutorial Audio Cassette with Samples
PC SWL automatically decodes Morse code RTTY
AMTOR SITOR NAVTEX and ASCII

PC SWL lets you tune in on world press services, meteorological broadcasts, ham radio operators' coast-to-coast stations, aviation telex and much more digital action on the shortwave bands. Why pay for another expensive box when a simple interface and your PC can do the job?

ADVANCED FEATURES:
Tuning Oscilloscope
Digital Waveform Presentations
Auto Calibration and Code Recognition
Continuously Tunable Filter Frequencies
Variable Shift
Adjustable CW Filter Sensitivity
Unattended Capture and Printing
Integrated Text Editor
Integrated Log and Database
Shell to DOS applications
Seamless integration with PC HF Fax/Telex

Call or write for our complete catalog of products.
Visa & MasterCard welcome.

NEVER SAY DIE

Continued from page 80

me know if you run across any signs of life.

Psyne

What's been your contribution to the world . . . so far? It's probably just the result of another bit of deformed DNA, no doubt resulting from my father smoking before I was conceived (it was Fatimas then, but it was Camels that eventually killed him), but I've always had this weird urge to somehow contribute something to the world during my short visit. It has to be a genetic problem because I don't ever recall any philosophical discussions along this line with anyone in my family. Or theological either.

Progress seems accepted as being beneficial, so I've always been inclined to do what I could within my limitations to help the world progress. My contributions have admittedly been minuscule, but satisfying to me.

How about you? Have you a feeling on some level that you owe the world a little positive push, or are you satisfied to be just a taker?

There are plenty of things you could do which would put a little more positive spin on our world. It's probably too late to get you to learn to write so you can help others to find out about interesting things, or even just enjoy what your mind provides for them. But, be-

ing a ham, there are a ton of scientific areas you could research and help pioneer. You've got a basic understanding of technology which could be put to excellent use. If you don't, you should have. That's part of your ham responsibility. I hope you haven't been cheating on this.

One area wide open for scientific investigation, one which doesn't even have to be expensive to pioneer, is the field of subtle energies. I like the term. I recently attended a conference in Monterey on the subject and was impressed with the progress that's being made. But even more, I was excited to find that this is such a new scientific field that almost anyone can get into it and produce worthwhile data. Yet I only ran into one ham at the conference. Tsk.

Subtle energies? What'n hell are they? That's the great part . . . no one really knows much yet.

Scientists have always been uncomfortable with anomalies. They really hate extra sensory perception and psychokinesis. They hate 'em so much that most scientists refuse to acknowledge that anything of the kind exists. Pathological skeptics. Having had enough proof in my own life that some sort of instant communications is possible over large distances; having had enough fortune-tellers read my tea leaves with incredible accuracy; and having read a hundred or so books about other carefully researched cas-

es, I've been impatient with scientists for so blindly ignoring all this data.

Reincarnation, the soul, past lives, out-of-body and near death experiences, UFOs, and so on are all scientifically unexplainable, despite endless detailed reports substantiating their existence. Of course one problem is the profusion of charlatans, both intentional and unintentional, taking advantage of the situation. Another is that even some of the better mediums fudge at times, trying to make up for the unpredictability of their gifts.

Despite the seemingly endless number of scams, many centered in La-La Land (aka Southern California), often dressed up in scientific-sounding baloney, down there somewhere there may be some important breakthroughs waiting for you to lift the right rock. As a registered skeptic I enjoy the hokum about scalar physics, subliminal tapes, hemisync tones, and so on. If you do get involved with this high weirdo stuff, try not to get swept up as a believer.

So I've put psy and science together to describe a still almost virgin field which is out there ready to be explored. Psyne. I like that better than psience. If you can harness psy, you'll have it made. ESP, clairvoyance, psychokinesis. Wow! It'll be a lot easier finding out how this stuff works than trying to disprove it, where you have millions of people who've had psychic experiences to face. The last statistics

I saw claimed that over 67% of Americans have had a psychic experience. So let's kick some sand in the face of the scientists who won't even try to explore psi and the other anomalies they're ignoring. My experience in Monterey is that you are not going to be alone.

Yes, there's a need for an honest communications medium . . . a publication . . . to help this new field develop. But with many of the potential ads being for unproved products and services . . . and I'm being very kind with that description . . . it's probably still a little early for a magazine. And where would I ever find people to honestly evaluate the products so we'd know what really works and what's baloney? Heck, science doesn't even have a clue as to how the placebo effect works.

So here's a field where the frontiers are still accessible. How does acupuncture work? How does ESP work? Where does herbal medicine fit in? Can rainmakers make rain? What about dowsing? There's a whole world of weirdness out there which needs honest investigation. So, if you have any pioneer spirit, and would like to contribute to the world, there's plenty to do.

Considering the state of scientific research today, you really couldn't ask for a better situation for the Independent researcher. You see, the modern scientist's success is measured by the

number of papers published. Being published results in grants, prestige, larger laboratories, and positions on decision-making committees.

One thing scientists know is that it is much easier to publish papers that don't challenge the present orthodoxy. As a result, few career scientists are interested in investigating anything which might cast a doubt on established beliefs. So they work over and over on smaller and smaller areas, and those generous grants keep coming. The end result is that science today has lost its spirit of adventure . . . and that leaves a wide-open opportunity for the amateur.

If you look back on history, almost all of the major breakthroughs in science were made by amateurs. And most of them had to fight the entrenched scientific community of the day. It took years before scientists recognized the work of Max Planck and quantum mechanics. As Planck pointed out, his new theories were not accepted by the scientists of his day, it's just that eventually the old scientists died.

There are whole worlds of science (and psynce) that are wide open for anyone with the guts and a never-say-die attitude.

Saving Amateur Radio

In line with my normal gloom and doom approaches to our hobby, I fear that, perhaps by accident, someone

will be appointed as an FCC Commissioner who has at least a slight grasp of communications and is not just reaping a political reward. As a result, the legitimacy of our exclusive rights to several billion dollars worth of public radio frequencies might be challenged. My proposition is simple: I suggest we spend a little time building at least a feeble leg to stand on should such a day of reckoning surprise us.

You might want to suggest this to your ARRL directors and see how far you get with them. Something like this might give you a hint as to how much of a voice you really have with the League.

Fortunately, past Commissioners in recent years have been too wrapped up with avoiding more mighty matters to notice us, so we've been sailing along in the foolish belief that it is our good works that have preserved our hobby. My thesis is that we'd better damned well re-invent our hobby before the Commissioners notice that we're no longer paying our dues.

I've been enjoying what is essentially another generous government hand-out . . . the use of our bands . . . but I keep wondering how long it's going to be before the piper comes around, wanting to be paid. One of these days some Japanese firm pushing a new satellite communications system is going to need some channels for the service and is going to start looking closely at all those lovely megahertz we're

not using and figure which senators and congressmen will have to be bribed to get those frequencies more productively allocated. Less than one million dollars invested in the right congressional re-election campaigns could free up several billion dollars worth of channels. Our government is famous for outstanding bargains when it comes to congressional bribery. And who were some of the biggest collectors of these bribes in the recent past? Secretary Bentsen and VP Gore!

Hmm, come to think of it, I've been a registered lobbyist for around 20 years or so. Maybe there are some companies who'd like to have some help in getting tons of radio channels so they can sell the equipment to use them? No problem, I know exactly how to go about it.

In my past gloom and doom editorials I've suggested a new reason for our existence, other than the dubious proposition that well, we were a help many years ago. We have to remember that gratitude is one of the least felt of all human emotions and stop betting our whole hobby on it. I've recommended that we establish ourselves in the role which was so successful for us in the 1950s, as the major supplier to our country of high-tech career-oriented youngsters.

In line with this I've been encouraging ham clubs to not just accept youngsters, but to go out and get them. I've some further ideas along

this line. I'd like to see the main club activity be the promotion of the hobby instead of just a meeting place for old-timers to kvetch about how bad the bands have gotten lately, what with all those lousy no-coders and everything, and how we need to raise the entry license to 50 wpm, not get rid of the code, and keep out the damned riff-raff.

In the days before the ARRL's Incentive Licensing proposal to the FCC, we had over 5,000 school radio clubs. Now we have only a few hundred left. So what I'm proposing as a major ham club activity is the re-establishment of school radio clubs, under the guidance of local ham clubs.

The school clubs should meet at least once a week. The youngsters would be invited to attend the local ham club monthly meeting where there would be show-and-tells on all of our main ham activities, such as DXing, CW, packet, RTTY, SSTV, repeaters, QRP, satellite communications, moonbounce, ATV, foxhunting, and so on. Then how about a short technical talk on AC, DC, tuned circuits, antennas, feedlines, and so on?

If there a half dozen schools in your area, each might have 20-30 members, and you might be able to get maybe 10 from each school club to come to your club meetings, if you keep 'em interesting. If we only got five new hams each per year out of 50,000 school radio clubs, we'd be adding

here is the next generation Repeater MARK 4CR

The **only** repeaters and controllers
with **REAL SPEECH!**

No other repeaters or controllers match Mark 4 in capability and features. That's why Mark 4 is the performance leader at amateur and commercial repeater sites around the world. Only Mark 4 gives you Message Master™ real speech • voice readout of received signal strength, deviation, and frequency error • 4-channel receiver voting • clock time announcements and function control • 7-helical filter receiver • extensive phone patch functions. Unlike others, Mark 4 even includes power supply and a handsome cabinet.

Call or write for specifications on the repeater, controller, and receiver winners.

MICRO CONTROL SPECIALTIES

Division of Kendecom Inc.
23 Elm Park, Groveland, MA 01834

Create messages just by talking. Speak any phrases or words in any languages or dialect and *your own voice* is stored instantly in solid-state memory. Perfect for emergency warnings, club news bulletins, and DX alerts. Create unique ID and tail messages, and the ultimate in a real speech user mailbox — only with a Mark 4.

2 meters 220 440

250,000 new hams a year to our hobby, and you'd make it much more difficult for me to zip down to Washington and sell out our bands to the highest bidder.

I wish I were exaggerating about how easy it would be to take hundreds of megahertz away from us. And just one attack like that could get the FCC to thinking about how much trouble we are and how little we offer. In return for all that aggravation. The next thing you know, pffft. Say, who could we sell our old ham rigs to? I suppose we could put 'em up on 11 meters and join the happy HFers. Yet, considering the sophistication of today's direction finding technology, I dunno.

How much is your ham ticket worth to you? Would you sell it for \$100, with the understanding that you'd never operate again? How about a \$1,000? What's your price? Okay, I know you've got a price, so we're just haggling. Let's say that the average ham will sell out for \$10,000. Then, how much would you be willing to pay to get a license? How much are your ham privileges worth to you?

Some DXers think nothing of spending \$100 just to get a new country. We've had hams travel around the world making a business of this. No "donation," no QSL. I've been hamming for so many years I can remember when a "Green Stamp" was a dollar bill. Now, if you want that rare DX QSL you'd better enclose a \$20 bill.

If your amateur radio license has a value for you, how much would you pay right now to preserve your privileges? Would you spend \$10 a year? \$50? \$100? Yes, I know, you're a member of the League and they're supposed to be preserving the hobby. Other than threatening to sue the FCC every now and then, in what way are they doing this preserving? I haven't seen them doing diddly to get our crummy bands cleaned up. And that despite the creative ideas I've proposed to help them. Too much trouble, I guess. Let's wait until the FCC really gets fed up with the mess we're making and then sue them if they try to give our frequencies to some outfit willing to buy them via generous gifts to Congress.

No, I don't know of any other outfit doing what needs to be done either, despite there being several almost invisible "national" ham groups. And no, I'm not asking for donations. If I get a big need for money I can go to Sony and explain how for maybe as little as \$20 million I can get them 20 MHz of choice microwave channels. Oh, make that \$50m, they've got the bucks and I'll need a little extra to do the usual hidden video of my talks with Congress' best. That'll give me something to show at hamfests.

I suppose I'd better put a little disclaimer in here, just in case someone is dumb enough to think I'm serious. We don't give IQ tests as part of the li-

cense exam, so now and then I get some really weird letters. I'm often tempted to try and explain that at times I use irony, sarcasm, and even whimsy, to get across a point.

So no, I'm not here with my begging bowl in hand. But instead of asking you for money, I am asking you to cough up some time. Time to either get your local ham club to get into action or to put together a putsch and take the club over so you can get something done. Sure, I wish you'd con a few of your friends into getting 73. If every reader recruited one more reader, we'd knock the socks off QST.

But I know what's going to happen. You're going to tell me you don't agree with everything I write and not chance any put-downs from friends who hate Wayne Green. Hate lovable old me? Lovable old "a spade is a spade" me? I suppose they're still mad at me for trying to get them to stop feeding that lard pile hanging over their belts, and trying to embarrass them into saying something of interest during QSOs.

Please let me know how you're doing on getting school radio clubs going, and send some pictures of the kids you con into trying our hobby. If I don't see pictures I'm not going to believe you're doing anything.

Extraordinary Science Conference

While I was attending a Subtle Energies Conference in Monterey (CA), I came across a promotion piece for a

science conference in Colorado Springs. So naturally I zipped out to see what this was all about. The promotion promised all kinds of dumb science scams, but hey, if even one turned out to be worthy of investigation, it would be worth the trip.

The conference surprised me. First, the place was packed with hams. Wall to wall. They even had a ham rig set up and running, generating a comforting sideband garble in the background of their amplifier system for the speakers. Secondly, the hams weren't kooks. Third, some of the conference sessions were very interesting and well done. A couple of them almost got me excited. Alas, most of the rest were crackpots. I get annoyed when someone has this great invention . . . but darn, the prototype got busted on the way to the show . . . It was working just a few days ago. The chap then explains that he doesn't have any of those old letters after his name. After about one minute of talk I knew that anyway. Further, I knew right away that he'd never even bothered to learn the fundamentals of electricity.

So I sat through three days of poorly done videos and non-working demonstrations of preposterous machines. You start it with a battery and it'll generate a zillion watts of power. Sigh.

One of the bright spots was the opening speaker who talked about the experiences he'd had as a dentist with

KENWOOD HAM STATION SPECIAL!!! SAVE \$\$\$

KENWOOD TH-78A Dual-Band FM Transceiver

amalgam fillings and nickel crowns. I'll try to get his book for you and make it available through Uncle Wayne's Bookshelf. If you, or anyone you know, has any fillings or crowns, you've better read this book ASAP: *It's All In Your Head* by Hal Huggins DDS. These could well be causing you all kinds of miseries. The 50% mercury in those fillings leaches out into your system. It's enormously poisonous and can cause Parkinson's, leukemia, multiple sclerosis, diabetes, and so on. Life is tough enough without your having a mouth full of poison feeding into your system. Touch a sensitive milliammeter to your tooth filling and your tongue and see how much current your tooth batteries are generating. And when a battery generates voltage, some of the metal in the battery goes where? Into you, that's where. So why doesn't the ADA stop dentists from putting in amalgam fillings? If they ever admit the liability it could cost dentists billions. So dentists are continuing to poison us.

One of the most interesting and visual of the talks was by Bill Wysock N6UXW, who showed off a Tesla generator which flashed sparks for about 10 feet. If you've got a few bucks and would like to experiment with ultra-high voltages, you might want to look up Bill.

I was disappointed that so few in the audience spoke up to point out that the speakers were ignorant about their subjects. But then, I didn't either. I didn't know how to ask questions of someone with a power generating device who wasn't really clear about the difference between a volt and a watt. Most of these characters were looking for money to finance their work.

But there were enough interesting ideas there to keep an inquisitive ham busy for months. And some ideas could be developed into practical devices. As I pointed out to some young hams who were watching all this with eyes bugging, all you have to do is spend a few weeks learning the basics of electricity and you'll be ready to tackle some of these projects. AC and DC theory isn't difficult. Nor are motors and generators. And learning is exciting.

I might not have zipped out to Colorado Springs for the conference if the Second Annual Boulder Ragtime Festival hadn't been on the same weekend. The two cities are only about an hour and a half drive apart, so I did the conference all day and then drove to Boulder for ragtime concerts at night.

Scott Kirby had driven up there from New Orleans, where he plays on the street. Scott's now being introduced as the foremost interpreter of Scott Joplin in the world. He draws standing ovations. He'll be giving some concerts in San José in November, and later at the Fresno Ragtime Festival.

The disappointing thing for me about many of the ragtime festivals is that most of the performers seem to pride themselves on discovering long-lost rags to play. The reason they were lost is that they never were any good. Like all popular music, only about 1% is worth hearing twice. But oh, that 1%! The good rags are fantastic and addi-

At the Colorado Springs Extraordinary Science Conference. Standing (left to right): Tony Chellemi KD6IFC, Covina CA; Bill Wysock N6UXW, Monrovia, CA; Rosalie Sorrell KD6KSG, Covina, CA; Skip Juhasz WB2UFV, Colorado Springs, CO; and Jim Hardesty N2DRT, Ithaca, NY. Seated (left to right): W2NSD; Mike Dpersio KC2Q, Bradley Beach, NJ.

tive, but I doubt there are much more than a hundred of them that are winners.

So these performers exhume the dead and foul up the festivals. They're tired of playing Joplin's "The Entertainer" and "Maple Leaf Rag," but guess what the audience wants to hear? They want to hear the good stuff over and over. There are about 20 of Joplin's pieces that bring tears to my eyes. They're what I want to hear.

The other superb performer at Boulder was Frank French. I've got to get him up to my studio and do a few CDs for you of him playing Gottschalk and Nazareth, and doing some of his monologues. If I can get you to try my Kirby CDs and a couple of French, you'll see why I'll fly to San José and then drive to Fresno to hear them perform. Or to Boulder.

Kirby recorded "More Damned Good Rags" in my studio this summer, plus some of his own rags. And he's got some corks.

Well, I had a great time at Colorado Springs at the conference and meeting the hams there, plus the concerts in Boulder. It was a great weekend. And if you old-timers would pay attention, you could meet me at things like this. You can buy a year's pass on Continental

Airlines if you're over 62... which most of you are by now. The pass costs about \$2,000 and lets you fly once a week for a year. For \$2,000 you can fly first-class all year. Yes, Continental flies to Dayton. So Sherry and I zip out to Las Vegas for the CES show, then Aspen for some skiing, and to various hamfests, electronic, computer and music shows. I have my Macintosh PowerBook with me, so I'm able to work wherever I am.

I've been under some pressure from friends to check into some networks, but I've avoided 'em so far. They can be time-consuming. Sherry checks into Prodigy, if you have any traffic for me. The new Prodigy rates seem to have their customers dropping out by the thousands.

Learn To Write

It's unfortunate that our schools don't teach kids to write. Oh, they can put a few words on paper, but that's not really writing. Writing takes some skill, and that means you need to learn how to do it. I don't recall ever being taught how to write, and I notice that the recent books about our school system have the same complaint. If you could see the mail I get you'd get a better

idea of how poor American writing skills are.

Yes, it takes some practice and some education, but once you learn it is fun to write. I'll bet you have a book in you, if you'd just let it come out. So get a laptop computer and one of the cheaper laser printers and make it easy. I've tried a bunch of laptops and like the Mac PowerBook best. And they're available used for peanuts these days. I bought a 4/40 Model 140 for under a kilobuck. That's with 4 megs of RAM and a 40 Mb hard drive. That should handle anything you'll need. With it you can answer mail in a couple minutes. You can write spec sheets, ads, manuals, newsletters, and even that book. Maybe some articles for 73? Once you try a laptop you'll never go back to a typewriter again. Or a pen.

An apology.

Apparently I have innocently offended one of the more militant homo-hams by my comments about homosexuality in my October editorial, in which I mentioned that I don't condone pedophilia... they're messing with children. The WSYI Report gaily leaped to defend homosexuality, writing: "Clearly, his behavior is abnormal... Green is to be pitied."

I'm not sure I've ever made any claims of being normal. I'm just not that deceptive. But no, I'm not normal. I don't sit home like most normal people, with a six-pack watching ball games on TV and eating pretzels. I don't even like beer, pretzels, or ball games. No one is going to call that normal, I hope. I apologize if I offended any child molesters with my editorial.

On the other hand, I sit on the bed and put my pants on both legs at the same time, just like everyone else, so there are many normal things about my life. And, like any true-blue ham, I've been active on OSCAR, have worked over 300 countries, helped pioneer NBFM, was an early user of SSB, RTTY, SSTV, and 6m, have made some unbeaten microwave records, have won all the bigger ham contests for my section, have DXpeditioned from dozens of rare countries, have done moonbounce work, have sat patiently through endless roundtables, have kerkchanked thousands of repeaters, and have helped tens of thousands of hams pass the stupid code test with my superb code tapes, which I just happen to think are better than any others anywhere. Only my overweening modesty prevents me from telling you how great I think they really are.

Well, as they say, any publicity is good publicity, so I appreciate what at first glance seems like just one more wearisome Green-bashing attack by WSYI. I also appreciate the letters from other homosexual hams apologizing for the hysterical and unwarranted attack on me by a lone over-motivated gay activist.

One more thing... I do wish that WSYI would not encourage hams to sue hams, even though it makes wonderful grist for his pinko paper and no doubt sells subscriptions.

SPECIAL EVENTS

Number 26 on your Feedback card

Ham Doings Around the World

DEC 4

FARIBAULT, MN The annual Courage Center Handi-Ham Winter Hamfest will be held at the Eagles Club, starting with registration at 8:30 AM. Flea Market. Handi-Ham Equipment Auction. Talk-in on 19/79. Contact *Don Franz W0FIT*, 1114 Frank Ave., Albert Lea MN 56007.

DEC 5

HAZEL PARK, MI The Hazel Park ARC will hold its 28th annual Swap and Shop, from 8 AM-2 PM, at Hazel Park High School, 23400 Hughes St. Talk-in on 146.64- (DART). Contact *HPARC, Box 368, Hazel Park MI 48030*.

SPECIAL EVENT STATIONS

DEC 3-5

SAN ANGELO, TX The San Angelo ARC will operate Station W5QX to celebrate Christmas at Old Fort Concho, from 0001Z Dec.3rd-2000Z Dec. 5th. Frequencies: Lower General portions of 40, 20 and 10 meters. For a certificate, send QSL with contact number and a 9 x 12 SASE to:

W5QX, P.O. Box 4002, San Angelo TX 76902.

DEC 4

FLINT, MI The Genesee County RC will operate W8ACW 1200Z-2400Z, to celebrate their 60th Anniversary. Operation will be in the General 80-15 meter phone subbands, the Novice 10 meter phone subband, and 2 meters. For QSL, send QSL and SASE to *GCRC, P.O. Box 485, Flint MI 48501*.

KALAUPAPA, HI Kalawao County will be on the air, with several SE Stations operating from the site of the Hansen's Disease Hospital, and the historic lighthouse. Phone, CW, and digital activities are planned for all bands, including the Novice subbands. Look for us at the lower portion of each subband. Listen for AH6IO, AH6IN, AH6KY, AH6KX, and others. For a commemorative QSL card, please send your card and an SASE to the home address of the operator contacted.

DEC 11

HOLLY, MI The Fenton Area ARA will operate KB8MBJ 1400Z-2400Z, during

Listings are free of charge as space permits. Please send us your Special Event two months in advance of the issue you want it to appear in. For example, if you want it to appear in the January issue, we should receive it by December 31. Provide a clear, concise summary of the essential details about your Special Event. Check Special Events File Area #11 on our BBS (603-924-9343). For listings that were too late to get into publication.

the annual Charles Dickens Festival. Operations will take place between 28.300/500 MHz and in the General portions of the 20 and 40 meter phone subbands. For a special card, send your QSL and #10 SASE to *Bill Coale KB8MBJ, 605 S. Broad St., Holly MI 48442*.

DEC 11-12

TROY, NY The Troy ARA announces its 2nd annual RTTY Sprint. The contest period this year will be from 2100 UTC Dec. 11th-0100 UTC Dec. 12th. Scoring and bands will be the same as the ARRL RTTY Roundup. Logs should be submitted by Jan. 17th, 1994 to *Bill Eddy NY2U, c/o TARA, 2204 22nd St., Troy NY 12180*.

DEC 18

PERRIS, CA Hams of the Orange Empire Railway Museum will operate KC6TKT and other calls 1900Z-2359Z, to celebrate their annual North Pole Limited Steam Train operation. SSB: 28.330 MHz. For QSL, send QSL and #9 SASE to *OERM, P.O. Box 548, Perris CA 92572-0548*.

DEC 18-19

NAZARETH, PA The Delaware-Lehigh ARC will operate W3OK 1400Z-0200Z Dec. 18-19, from the twin Christmas cities of Nazareth and Bethlehem PA. Frequencies: 3.965, 7.265, 14.265, 21.365, 28.365. For a certificate, send QSL and SASE to *DLARC, RD4, Greystone Bldg., Nazareth PA 18064*.

DEC 30-JAN 1

PASADENA, CA The Relay Repeater Club will operate Station WB6BNJ, from the Wrigley Mansion, Dec. 30th-Jan. 1st, from 1600Z-0200Z each day. Primary frequency will be 28.460 MHz. Secondary frequencies: 21.335 MHz and 14.260 MHz. This event is in conjunction with the 105th Anniversary of the Tournament of Roses. Amateurs in California/Nevada can contact the Station on 2 meters through the 147.21 repeater, on the half hour, or on 220 MHz, via the Condor Connection, on the hour. For a certificate, send a QSL, with contact number and a 9 x 12 SASE with 58 cents postage, to *Relay Repeater Club, P.O. Box 660081, Arcadia CA 91066-0081*.

Serving The LORD
Since 1987

\$49.95!

THE POWER STATION

The POWER STATION is a 12V x 6.5 AmpHr gel-cell battery complete with voltmeter, wall charger and a cord for charging via automobiles. It will power most

HT's at 5 Watts for 2-4 weeks (depending upon how long-winded you are). Also VHF, UHF, QRP, or HF mobiles such as the KENWOOD TS-50 (at 50W). There are no hidden costs, all you need is your mobile, HT power cord or cigarette lighter adapter.

The POWER STATION provides 12V from a cigarette plug and has two recessed terminals for hardwiring. A mini-phone jack with regulated 3V, 6V, or 9V output can be used separately for CD players, Walkmans, etc. THE POWER STATION can be charged in an automobile in only 3 hours, or in the home in 8 hours. The charger will automatically shut off when the battery is completely charged, so you can charge it even when it has only been slightly discharged, (unlike Ni-Cads that have memory). Our charging circuit uses voltage sensing circuitry, other brands are timed chargers which always charge the battery a full cycle, this damages their battery and shortens its' life if it only needs a partial charge. The POWER STATION has a voltmeter that shows the exact state of charge of the battery, not worthless idiot lights that tell you "YOUR BATTERY IS NOW DEAD." The voltmeter can even be used to measure voltages of other sources.

To order, send check or money order for \$49.95 + \$8.50 for shipping, along with your shipping address and telephone number to:

Joe Brancato
THE HAM CONTACT
P.O. Box 3624, Dept. 73
Long Beach, CA 90803.

CA Residents Add 8 1/4% Sales Tax. Canadian Residents Please Send U.S. Money Order & \$17.10 Shipping.

If you wish more information please send a SASE to the above Address. For CORD orders, call (310) 433-5860, outside of CA call (800) 933-HAM4 and leave a message.

David Cassidy N1GPH

Peace

It is the time of the year when all the world's peoples contemplate brotherhood, goodwill, and peace. Maybe it would do us some good if we could stop contemplating it and start doing it. The world sure is a mess!

In the last year, the former Soviet Union narrowly missed yet another attempt by the old guard to return to the repressive policies of the past. The people of Russia are still coming to grips with the fact that freedom costs.

The beautiful country of Bosnia (formerly Yugoslavia), host to the Winter Olympics just a few short years ago, has been literally destroyed by religious and tribal bigotry. The faces of the children of Sarajevo tell the story.

Botched policy in Somalia has resulted in the deaths of several American (and other) citizens. We went there in peace to do our duty as the leader of the free world. We saved millions from certain death, and the citizens of Mogadishu have paid us

country have escalated their message with intimidation and bullets. Can you believe this war has been going on now for 20 years?

The current ruling party has decided that the fact that Socialism has failed miserably in Eastern Europe shouldn't deter the United States from giving it a try. Clinton Administration policies (and the fear of what's next) have essentially paralyzed an already failing U.S. economy. In the name of "fairness," the American people appear to agree that they should give up some of their hard-won freedoms. There's enough pork in the barrel for both political parties, so the Republicans cannot claim any philosophical high ground, either.

Are there glimmers of hope in all this? Sure. For the first time since Moses came down from Mt. Sinai, Arabs and Israelis have met and agreed to at least try to live together without bashing each other's heads in. This is peacemaking at its most basic level. These two groups have agreed that the other has the right to exist. It ain't much, but it's a start.

"Once again, the good intentions of the United States are being answered with the barrel of a gun."

back by dragging the dead bodies of American soldiers through their streets.

Haiti is exploding even as I write these words (in mid-October). Once again, the good intentions of the United States are being answered with the barrel of a gun.

The mess hasn't avoided the streets of America, either. The judicial system in the State of California has abdicated its power. The so-called "leaders" of the minority groups living in the Los Angeles area, the very ones who should be concerned with uplifting and providing opportunity for people, are the very ones who make excuses for thugs and criminals. Instead of rule of law, California has instituted rule by mob. Threats of violence and riots seem to be the ways to get what you want out of the California Courts.

This year, for the first time, terrorism reached the shores of America in the form of the bombing of the World Trade Center.

While crimes against tourists are actually on the decrease in Florida, the news media decided to create a crisis so that foreigners are now afraid to vacation here.

The anti-abortion forces in this

My mother is the choir director at her church. When I was young, my brothers and I all sang in her choir. One Christmastime, she taught us a song that is based on The Prayer of St. Francis of Assisi. I'd like to offer the words to this song as my holiday gift to you:

Lord, make me an instrument of your peace.

Where there is hatred, let me sow love.

Where there is injury, pardon.

Where there is doubt, faith.

Where there is despair, hope.

Where there is darkness, light.

Where there is sadness, joy.

Oh, Divine Master, grant that I may not so much seek

To be consoled, as to console,

To be understood, as to understand,

To be loved, as to love.

For it is in giving, that we receive, And it is in pardoning, that we are pardoned,

And it is in dying, that we are born, To eternal life.

No matter what your religious beliefs, the truth is still the truth.

I wish you peace. Shalom.

Jim Gray W1XU

Jim Gray W1XU

Payson AZ 85541

In spite of the decline in sunspot activity, December ought to be a Good month for propagation on the HF bands. The daily chart shows only the 12th and 13th and again the 27th to be Poor days. All the rest of the month will be characterized by many days of decent propagation... the first month like this in a long time. The P (Poor) days may also be accompanied by severe weather conditions.

Of course, you can't rule out an unexpected and sudden disturbance sometime during the month, but it doesn't seem likely except on the days marked P (Poor) or trending between F (Fair) and P (Poor). Times given below are LOCAL times, but the Band-Time-Country chart uses Coordinated Universal Time (what used to be called GMT).

10 and 12 meter bands: Occasional morning openings to Europe, frequent midday openings to South America and Africa, and late afternoon openings to the South Pacific and Australia. Also, short-skip openings during daylight hours between 1,000 and 2,300 miles possible on Good days.

15 and 17 meter bands: Worldwide DX during daylight hours possible on Good (G) days, with bands peaking toward the EAST after sunrise, toward the SOUTH at midday, and toward the WEST during the afternoon hours. Short skip between 1,000 and 2,300 during daylight hours.

20 meter band: Once again, this will be the top DX band for December between dawn and sunset. The band will close earlier than during summer or equinox months, but you can expect excellent daylight DX. Also, short skip beyond 500 miles will be frequent during daylight hours.

30 and 40 meter bands: These bands are expected to open to the EAST during late afternoon and early evening hours, with excellent propagation for DXers on Good (G) days. The band ought to stay open for DX during nighttime hours and close shortly after sunrise. Short skip up to 1,000 miles during daytime and beyond 1000 miles at night, when the band "goes long."

80 and 160 meter bands: You will find much DX and LOW NOISE on many days of the month, with DX peaking toward the EAST around midnight and peaking in various directions just before sunrise local time. Daytime short skip of around 500 miles on 80 meters and over 500 miles at night should prevail on Good (G) days.

On 160 meters, there will be NO daytime propagation, due to heavy absorption of signals by the ionosphere. Occasional DX between dark and sunrise should be possible on Good (G) days, but as always—QRN will be a limiting factor. Short skip up to about 1,000 miles during nighttime hours can be expected... sometimes even when static is heavy.

Grey-line propagation: During the hours surrounding sunrise and sunset (local time) you may be able to take advantage of grey-line skip to the parts of earth in the "fuzzy" areas between total dark and total daylight. Try all the HF bands during these times for unusual signal strength to and from unexpected areas. See you next month, W1XU.
